

SIMULATION OF METEORS FOR THE JEM-EUSO EXPERIMENT

CANDIDATO: Fabrizio Gola

RELATORE: dott. Mario Edoardo Bertaina

CORRELATORE: dott. Alberto Cellino

Meteor of the Perseids observed from ISS (Aug. 2011)

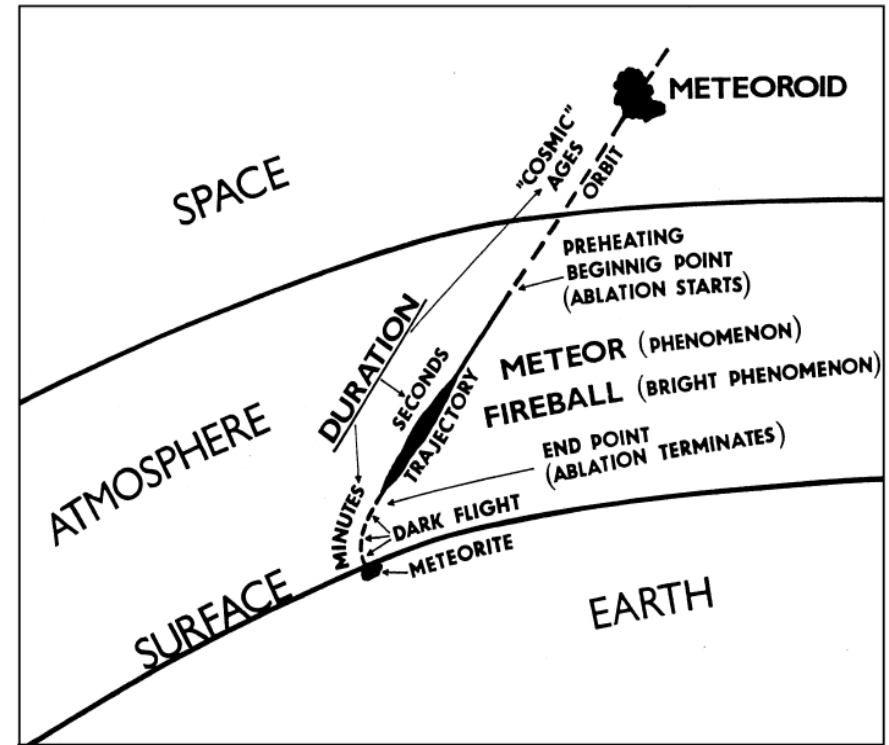

JEM-EUSO on ISS

There are good reasons to study the so-called Near-Earth Objects (NEOs)

$$1 \text{ MT} \sim 4.18 * 10^{15} \text{ J}$$

- **Beginning point:** $\sim 75 \div 120$ km
- **End point:** $\sim 30 \div 70$ km
- **Duration:** $\sim 0.5 \div 3$ s
- **Length:** $\sim 10 \div 20$ km
- **Type:** sporadic, showers ($\sim 25\%$ obs. meteors)
- **Frequency:** $\sim 5 \div 100$ per hour (up to thousands during meteor storms)

Visual meteors

meteoroids with $D > 2$ mm

The Peekskill fireball (Oct. 9, 1992)

m < - 8 **bolide or fireball** (meteoroid mass 10 ÷ 100 kg)

m < - 17 **superbolide** (meteoroid mass > 1000 kg)

Fireball precursors, between 10 m and 100 m in size, are the least known population of minor bodies in our Solar system

What we need to know about meteoroids

- Mass
- Density → Luminosity, deceleration, ablation equations
- Structure → Beginning and terminal heights
- Composition → Spectra + analysis of recovered meteorites
- Orbit → Velocity vector
- Flux → Direct observation

We want to obtain data on largest bodies observable in the atmosphere, filling in the missing data between 10^3 and 10^6 kg mass interval

FONT: JEM-EUSO Meteor Observation by Watanabe, Ishiguro, Sato (13/06/2009)

ABSOLUTE MAGNITUDE	U-BAND FLUX (erg/s/cm ² /Å)	FLUX (ph/s)	FLUX (phe/GTU) [1 GTU = 2.5 μs]	MASS (g)	COLLISIONS IN THE FIELD OF VIEW OF JEM-EUSO
+7	6.7*10 ⁻¹²	4.3*10 ⁷	11	0.002	1/s
+5	4.24*10 ⁻¹¹	2.7*10 ⁸	68	0.01	6/min
0	4.24*10 ⁻⁹	2.7*10 ¹⁰	6750	1	0.27/orbit
-5	4.24*10 ⁻⁷	2.7*10 ¹²	675000	100	6.3/year (duty cycle 0.2)

flux=flux from Magnitude/Flux Density Converter of Spitzer Science Center (photometric system Johnson UBVRI+ in the U-band)

ph = photons

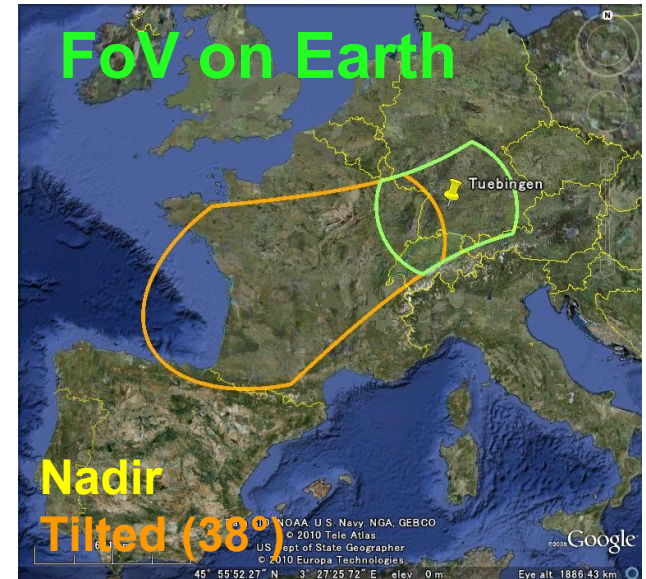

phe = photoelectrons

What is JEM-EUSO telescope

MISSION PARAMETERS

- **Time of launch:** year 2017
- **Operation period:** 3 years (+2 years)
- **Launching Rocket:** H2B
- **Transportation to ISS:** un-pressurized Carrier of H2 Transfer Vehicle (HTV)
- **Site to Attach:** Japanese Experimental Module/Exposure Facility #2
- **Height of the Orbit:** ~ 400 km
- **Inclination of the Orbit:** 51.64 °
- **Latitude and longitude:** 51.6° N – 51.6° S (for all longitudes)
- **Power:** 926 W (operative), 352 W (non-operative)
- **Mass:** 1983 kg
- **Data Transfer Rate:** 285 kpbs + on-board storage
- **Period of the Orbit:** 90 mins

INSTRUMENT PARAMETERS

- **Field of view:** $\pm 30^\circ$
- **Aperture diameter:** 2.5 m
- **Optical bandwidth:** 330 ÷ 400 nm
- **Angular resolution:** 0.07°
- **Pixel size:** 2.9 mm
- **Number of pixels:** $\sim 3.0 \times 10^5$
- **Pixel size at ground:** 560 m
- **Event time sampling:** 2.5 μ s = 1 GTU
- **Observational area:** $> 1.9 \times 10^5$ km² (depending on the pointing angle)
- **PMT Gain:** 10⁶ (0.16 pC / phe)
- **Detector efficiency:** 0.12
- **KI partition:** rectangular (4 x 2 pixels)

Optics and electronics

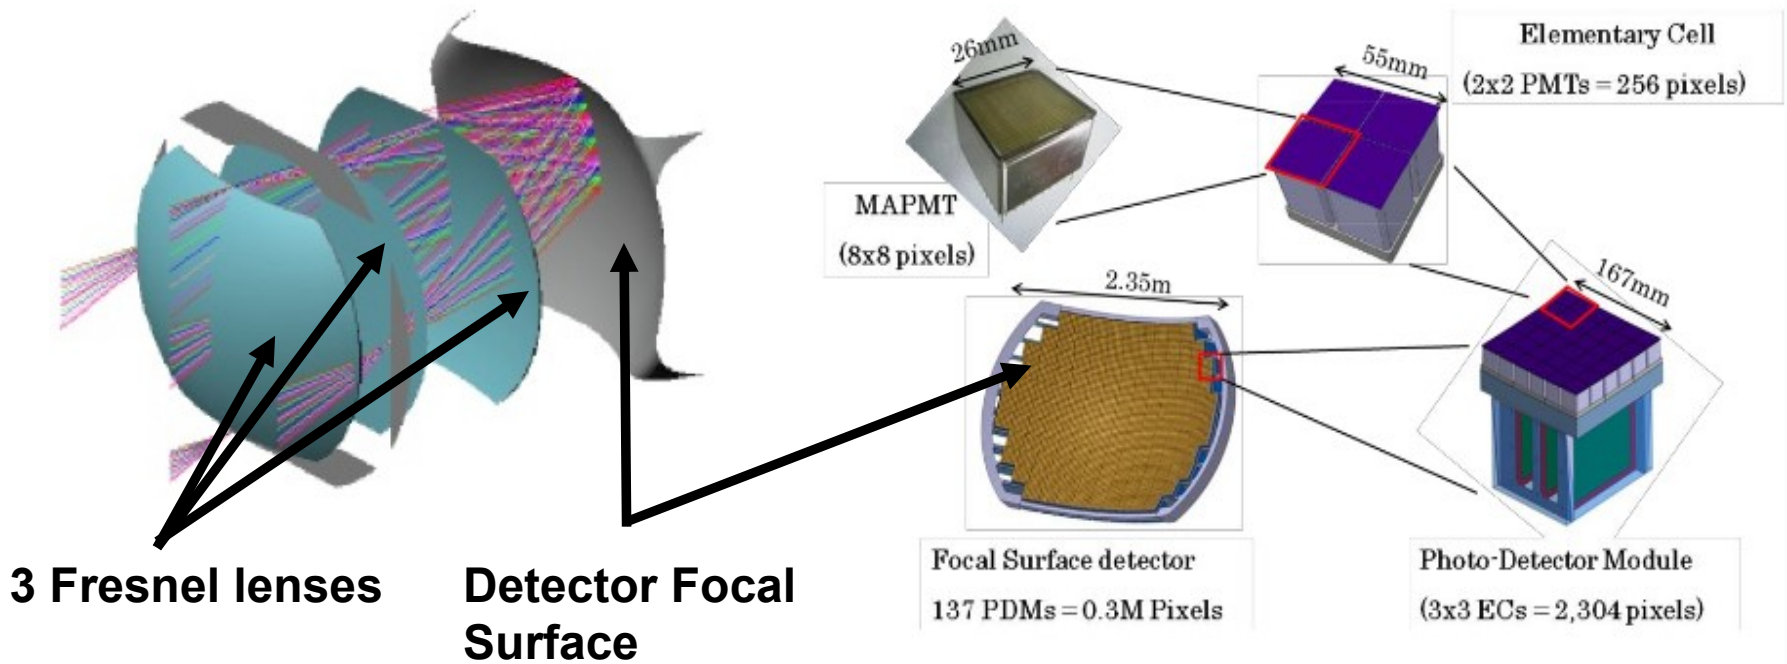

Figure 4.3.1-1. Focal surface detector and its structure.

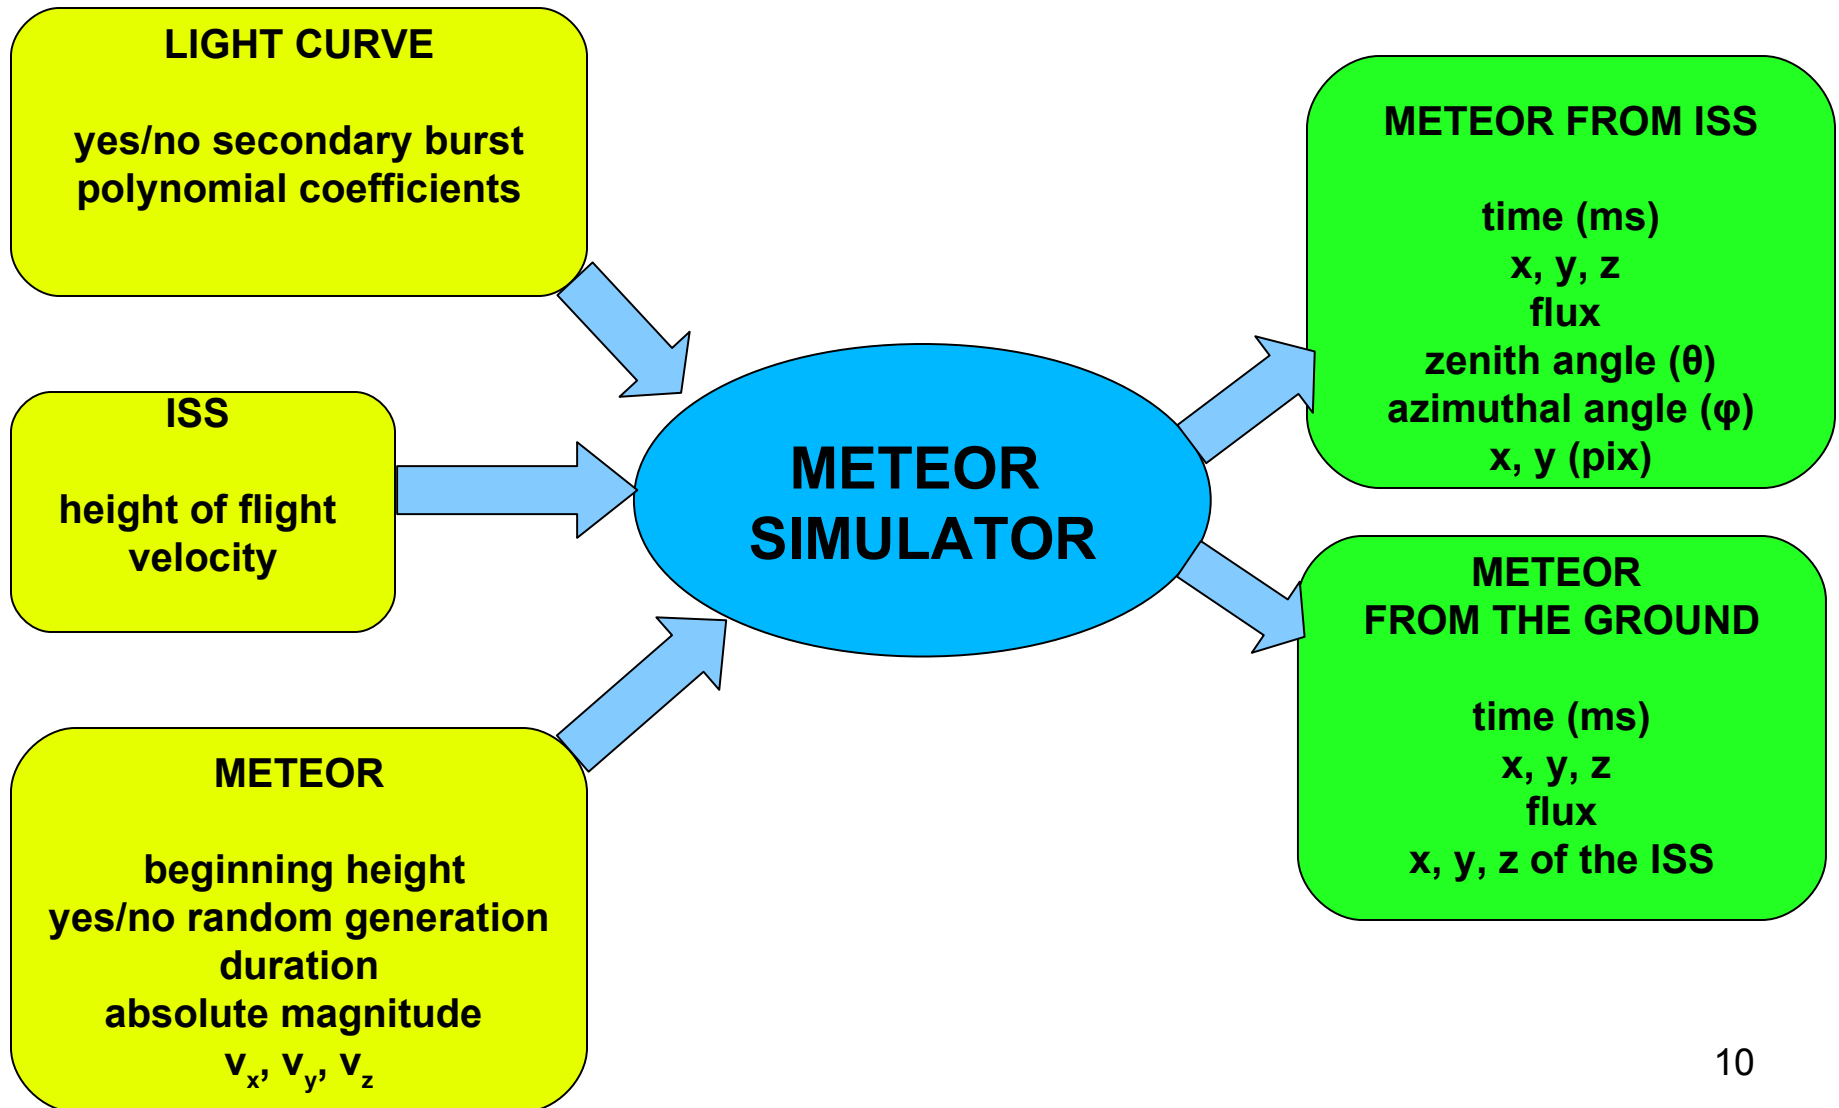

MAPMT

single KI pixel

Working mode:

ANALOG (charge integration)
KI pixels = 4 X 2 MAPMT pixels

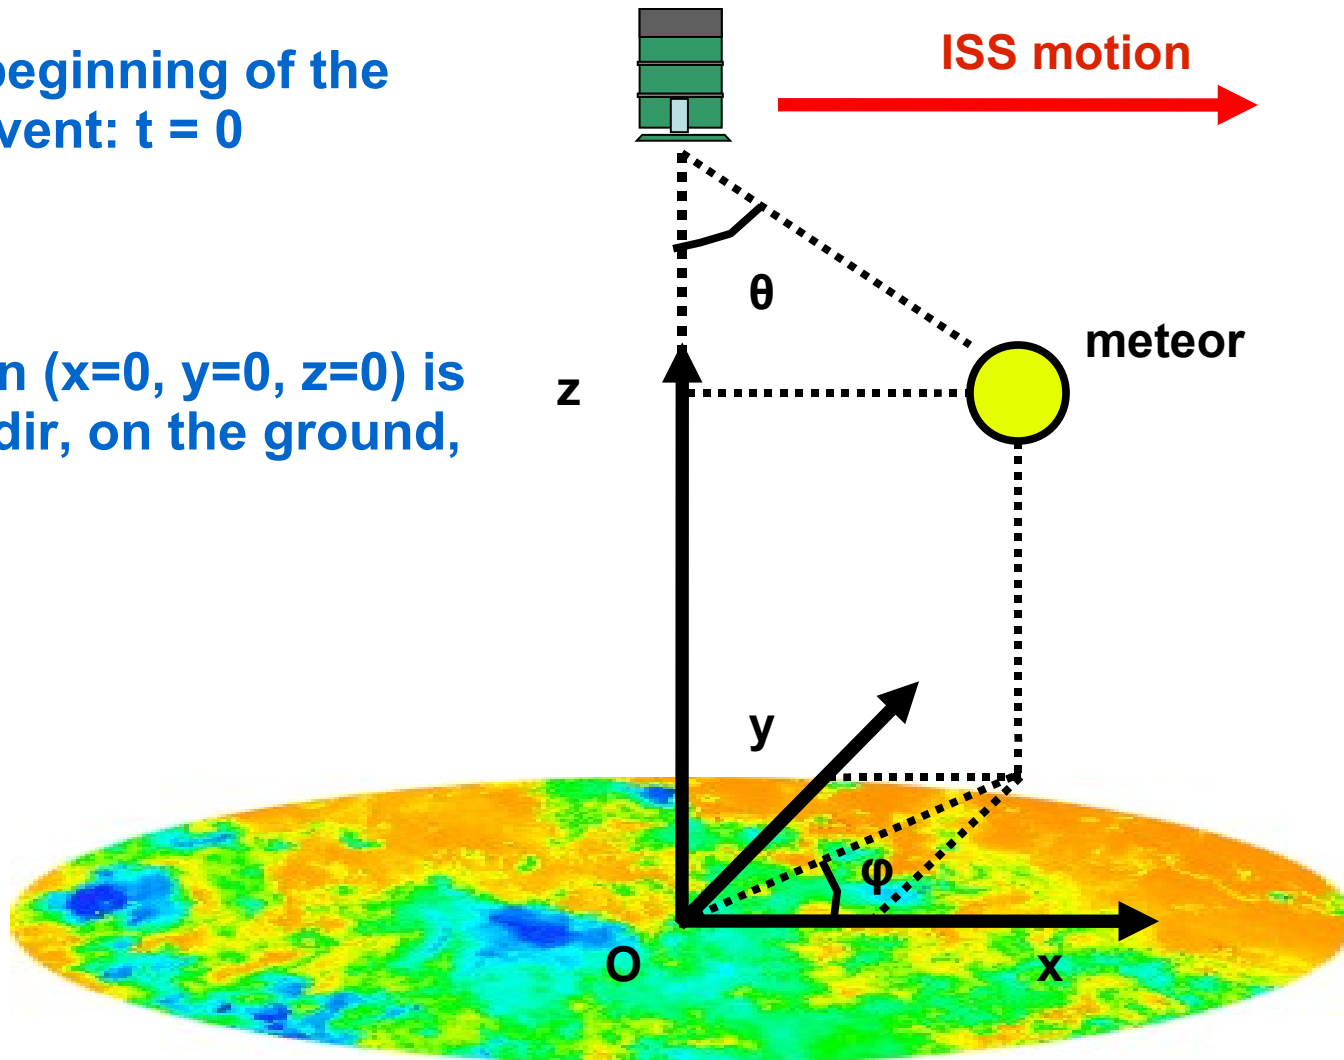

Meteor simulation

Reference system

Time of beginning of the meteor event: $t = 0$

The origin ($x=0, y=0, z=0$) is at the nadir, on the ground, at $t=0$

Meteor simulation: magnitude

Absolute magnitude

$$M = -2.5 * \log_{10}(\text{flux}) + C$$

$$C = 2.5 \log_{10}(6750) \sim 9.57$$

Apparent magnitude

$$m = M - 10 + 5 * \log_{10}(\text{dist})$$

$$\underline{1 \text{ GTU} = 2.5 \mu\text{s}}$$

$$[\text{flux}] = \text{phe} / \text{GTU}$$

$$[\text{dist}] = \text{km}$$

Our assumptions for a meteor profile (input parameters)

All simulated meteors have a secondary burst

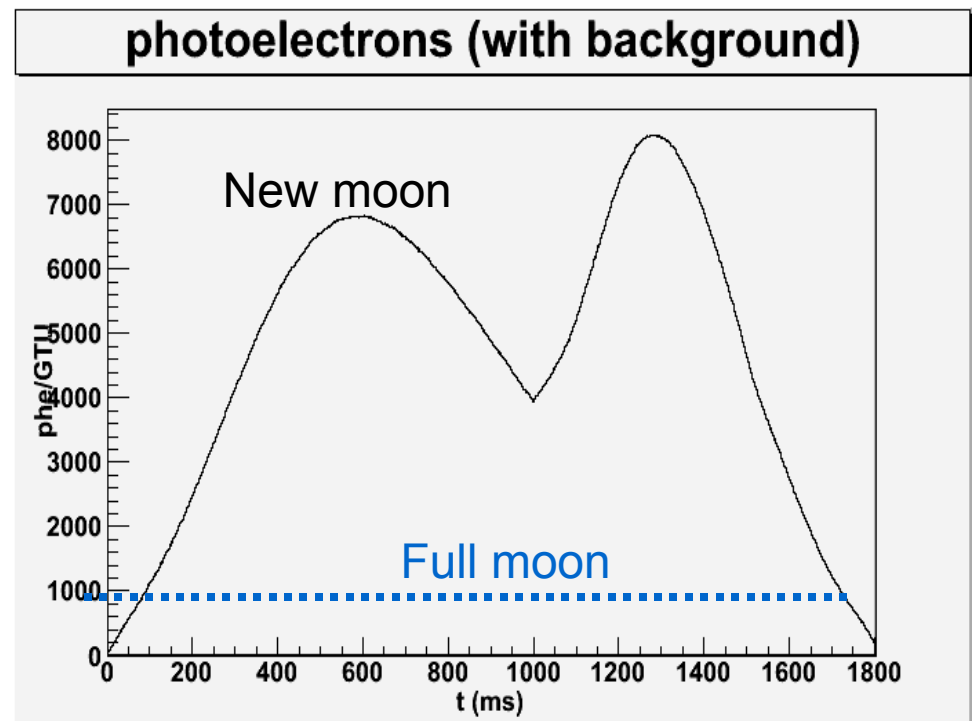

- **Height of the ISS:** 400 km
- **Velocity of the ISS :** 7.8 km/s
- **Beginning height of the meteor:** 100 km
- **Duration of the main event:** 1.5 s
- **Duration of the secondary burst:** 0.8 s
- **Beginning time of secondary burst:** 1 s
- **Duration of meteor:** 1.8 s
- **Shape of the light curve:** 8th degree polynomial (the same for both the main event and the secondary burst)
- **Event time sampling:** 1 GTU = 2.5 μ s

The signal is modulated for every ms and integrated for a single GTU, in a single KI

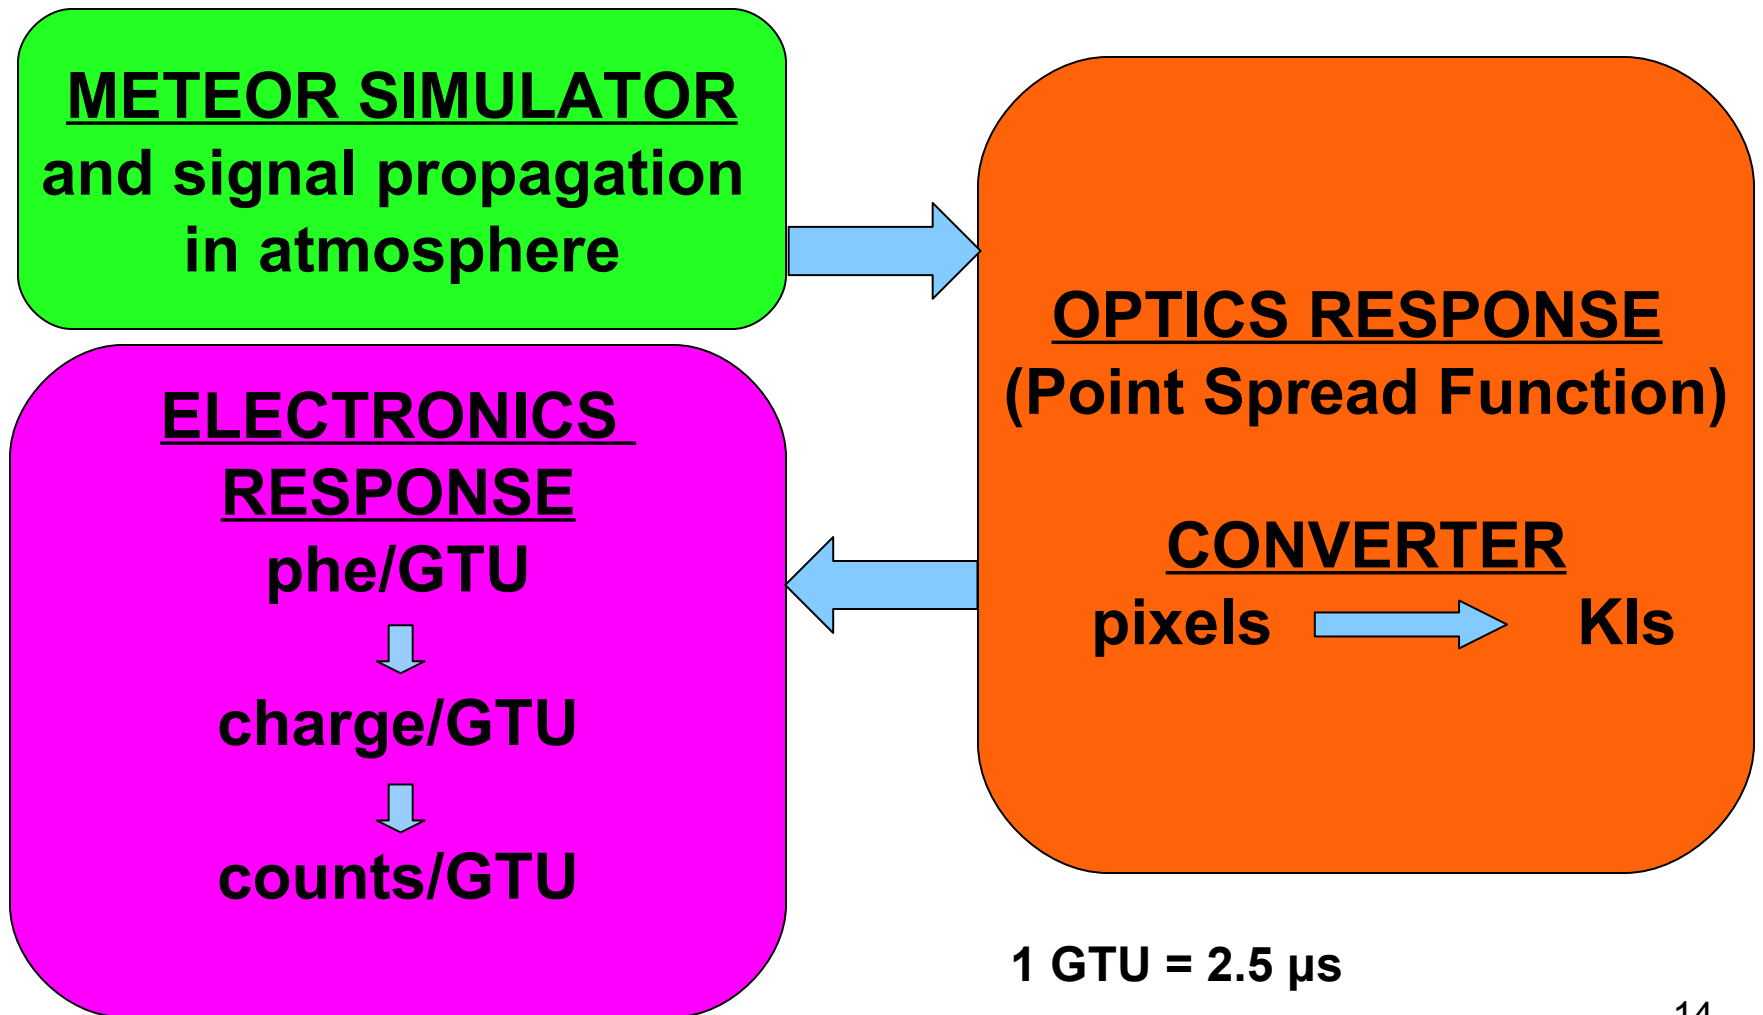

Approximations:

- **NO PERSISTENCE**
- **NO DECELERATION**
- **NO ABSORPTION COEFFICIENT OF THE AIR**
- **POINT- LIKE SOURCE**
- **LIGHT CURVE = UV LIGHT CURVE**

METEOR LIGHT CURVE (M=0)

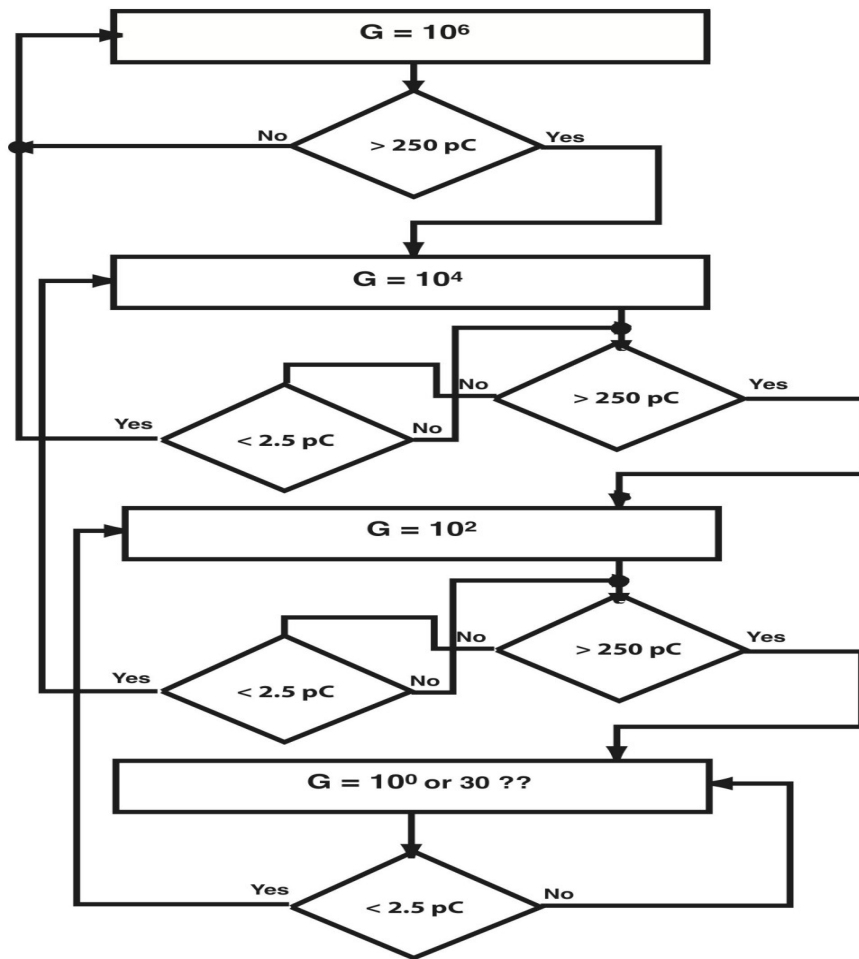

From meteor simulation to the recorded signal

HV protection logic for intense signals

To avoid too strong currents in the MAPMT, a KI should not have more than 250 pC/GTU. The *switch-logic* elaborated by P. Gorodetzky reduces the gain within 2 GTUs of a factor 100 as soon as the threshold is exceeded in just one KI of the PDM. Only when every KI receives less than 2.5 pC the gain can be increased again.

Level	Gain
0	10^6
1	10^4
2	10^2
3	1

COMPLETE METEOR PROFILE

$$v_x = v_z = 0 \text{ km/s}$$

$$v_y = 20 \text{ km/s}$$

$$M = -5$$

projection of the signal on the focal surface

photoelectrons

maximum number of photoelectrons

$$1 \text{ GTU} = 2.5 \mu\text{s}$$

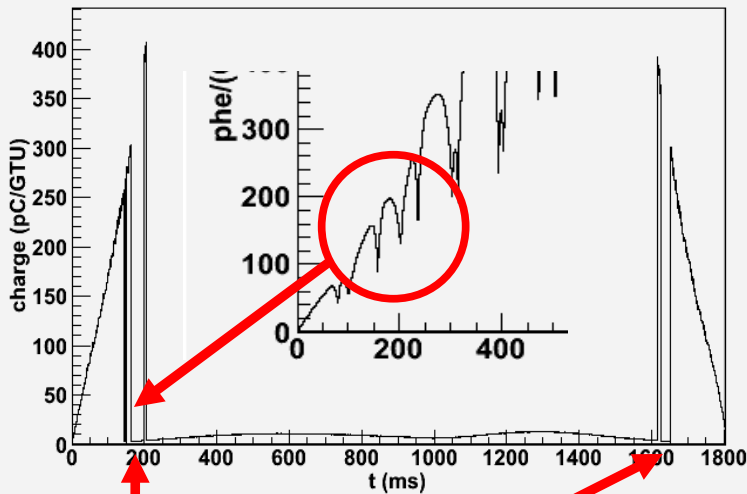

drawn photoelectrons (with background)

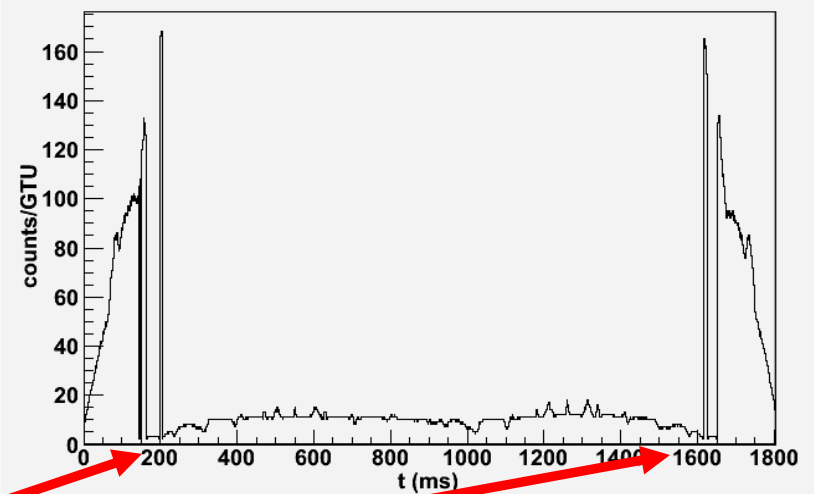

charge

charge (switch-logic)

ADC counts

Effects of the switch logic

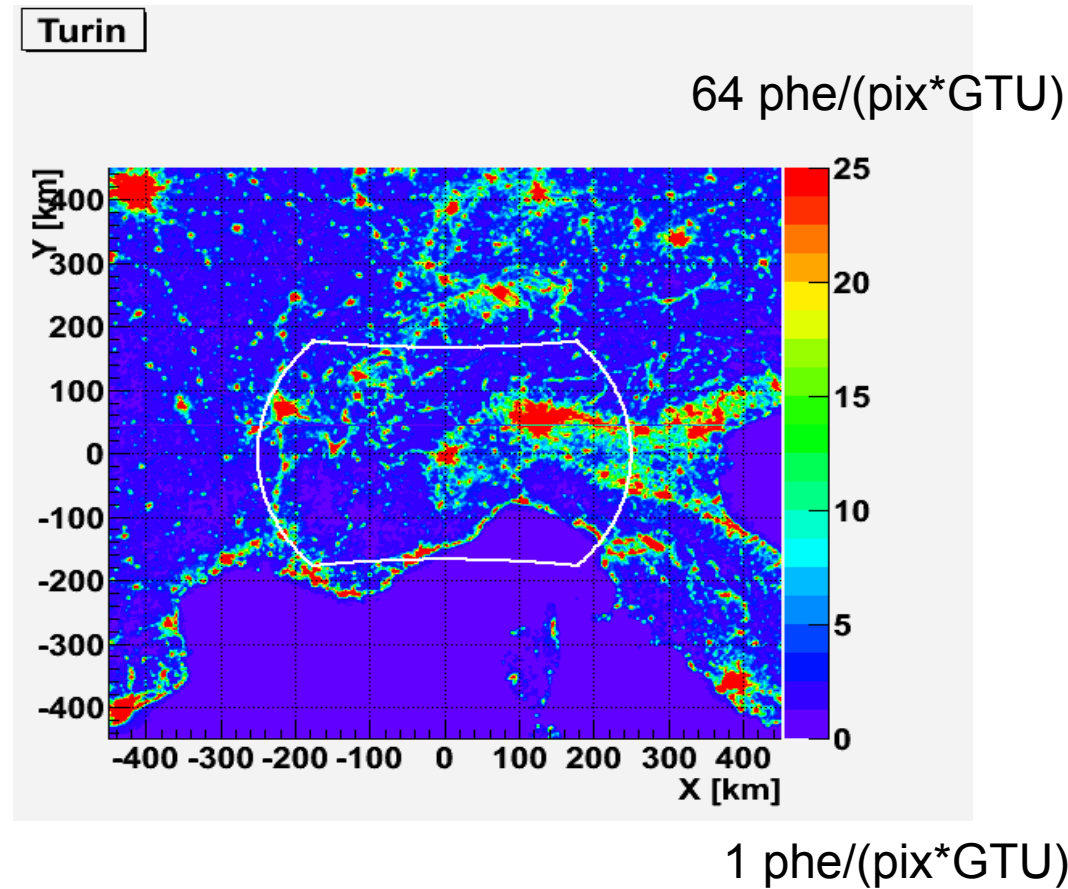

1 GTU = 2.5 μ s

Cities

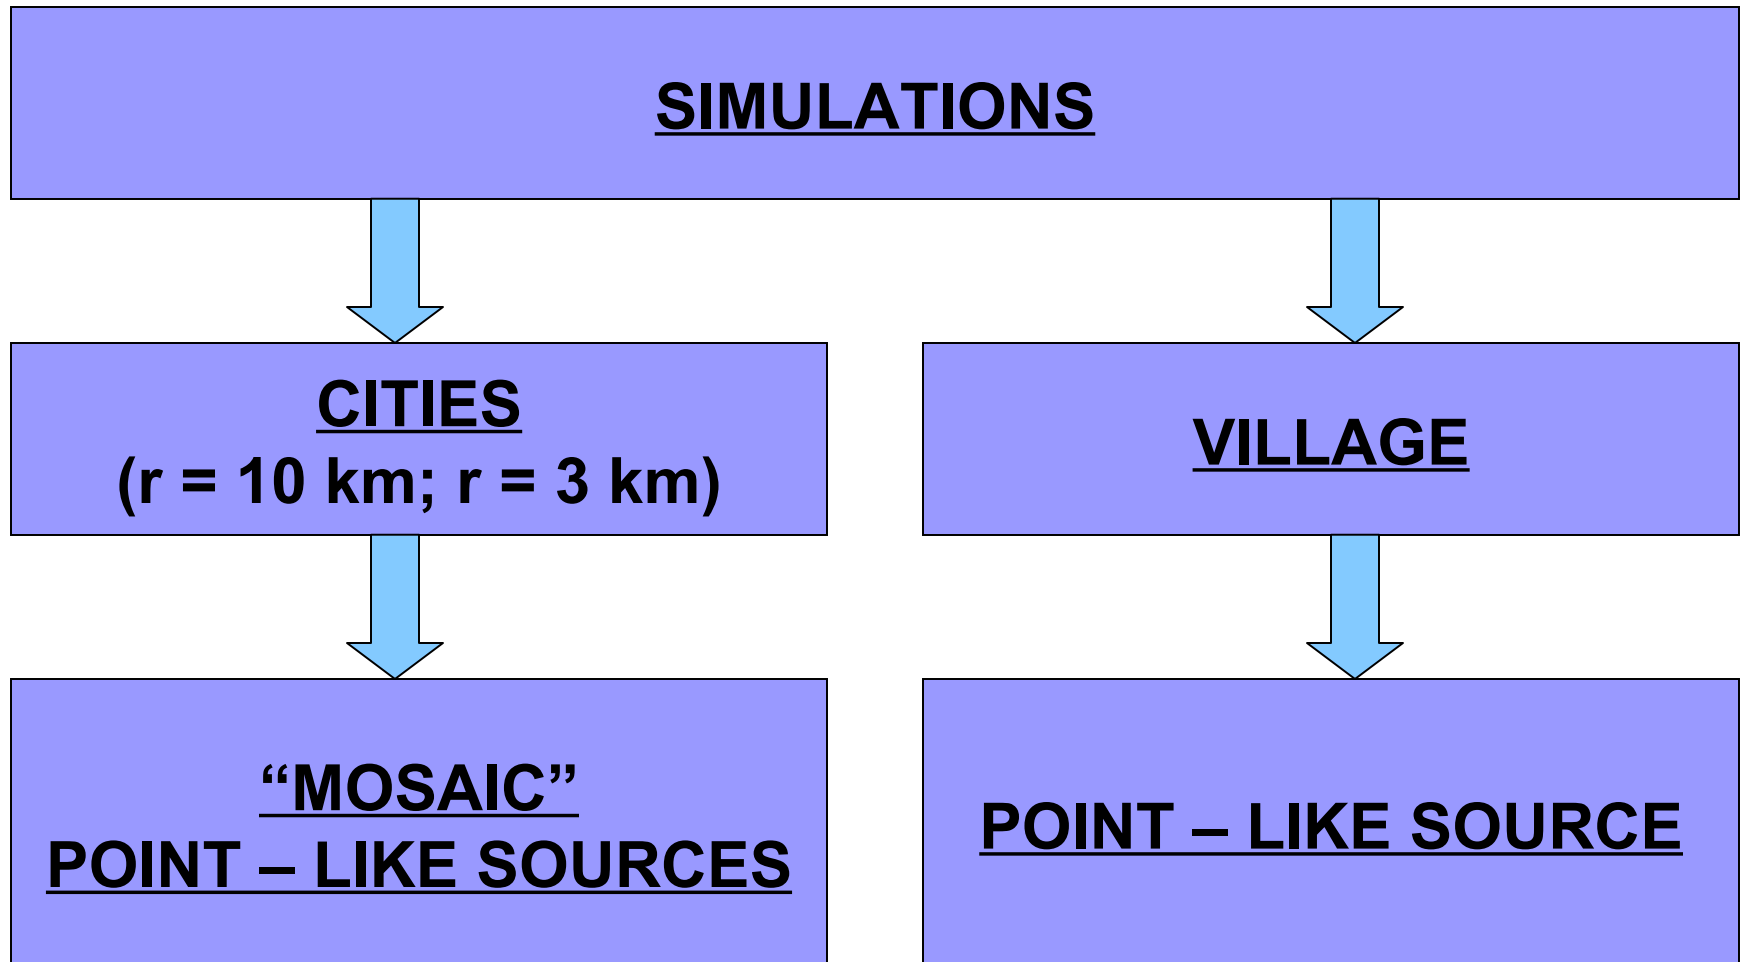

ASSUMPTIONS (INPUT PARAMETERS)

CITY = METEOR with:

- Beginning height = 0 km
- Constant light curve
- Circular shape
- No secondary burst
- $M \sim 5.06$
(flux = 64 phe/(pix*GTU))
- $v_x = v_y = v_z = 0$ km/s

SIMULATION OF CITIES: PSF

Cities vs vertical meteor ($M \sim 5.06$; $v_z = -11.2$ km/s)

$r = 10$ km

$r = 3$ km

projection of the signal on the focal surface

projection of the signal on the focal surface

Village

Vertical meteor

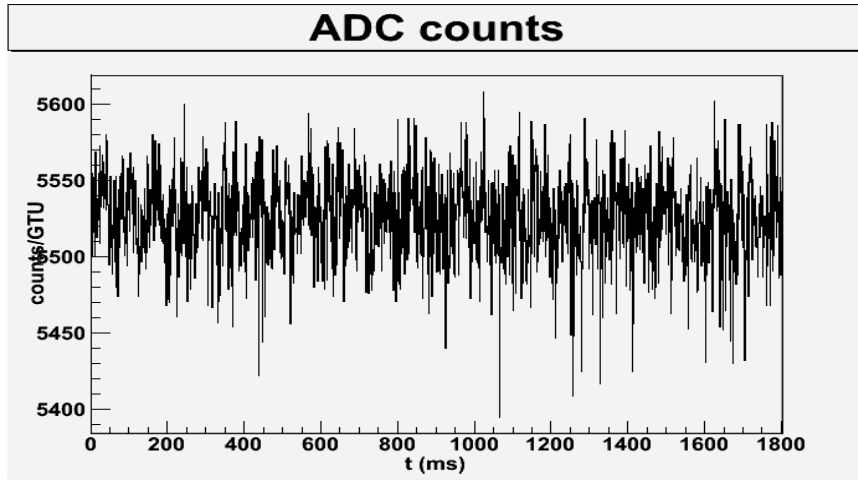

projection of the signal on the focal surface

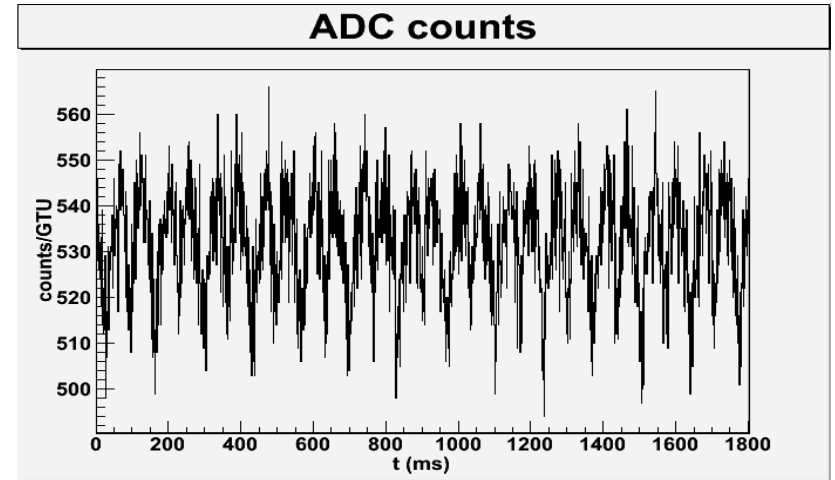

projection of the signal on the focal surface

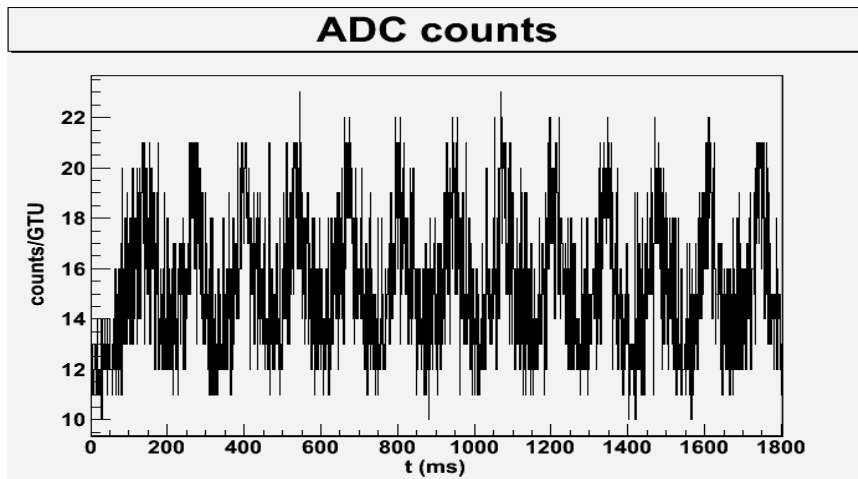

$r = 10 \text{ km}$

$r = 3 \text{ km}$

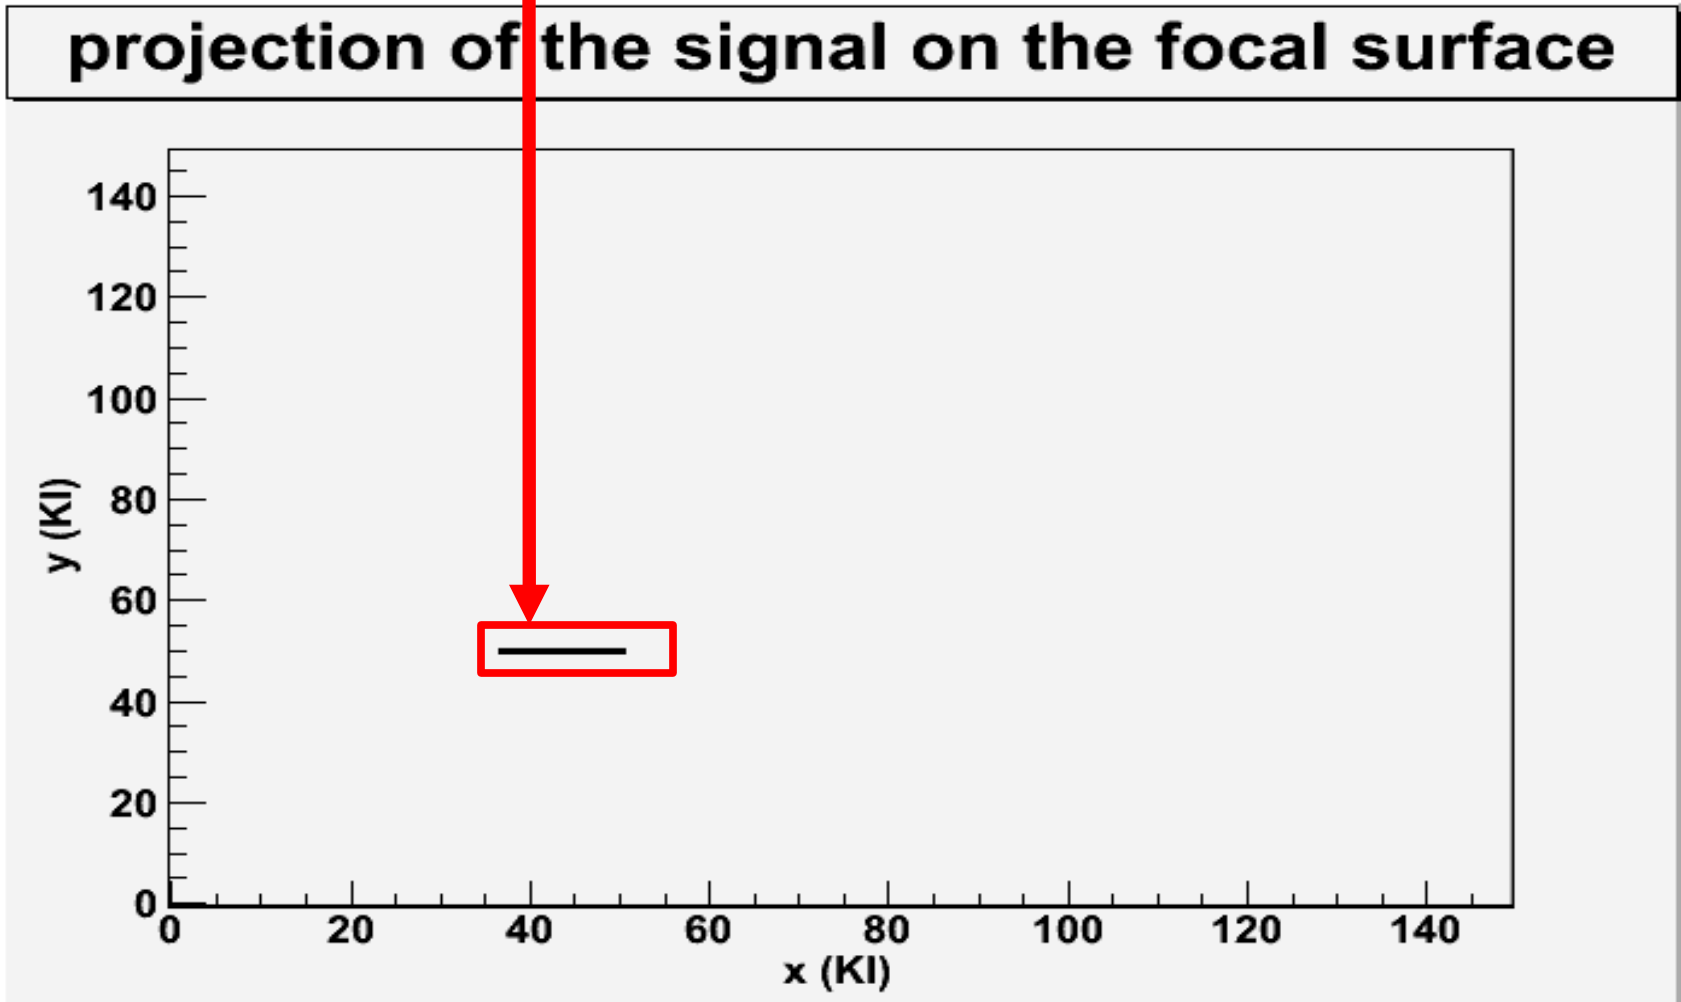

Village

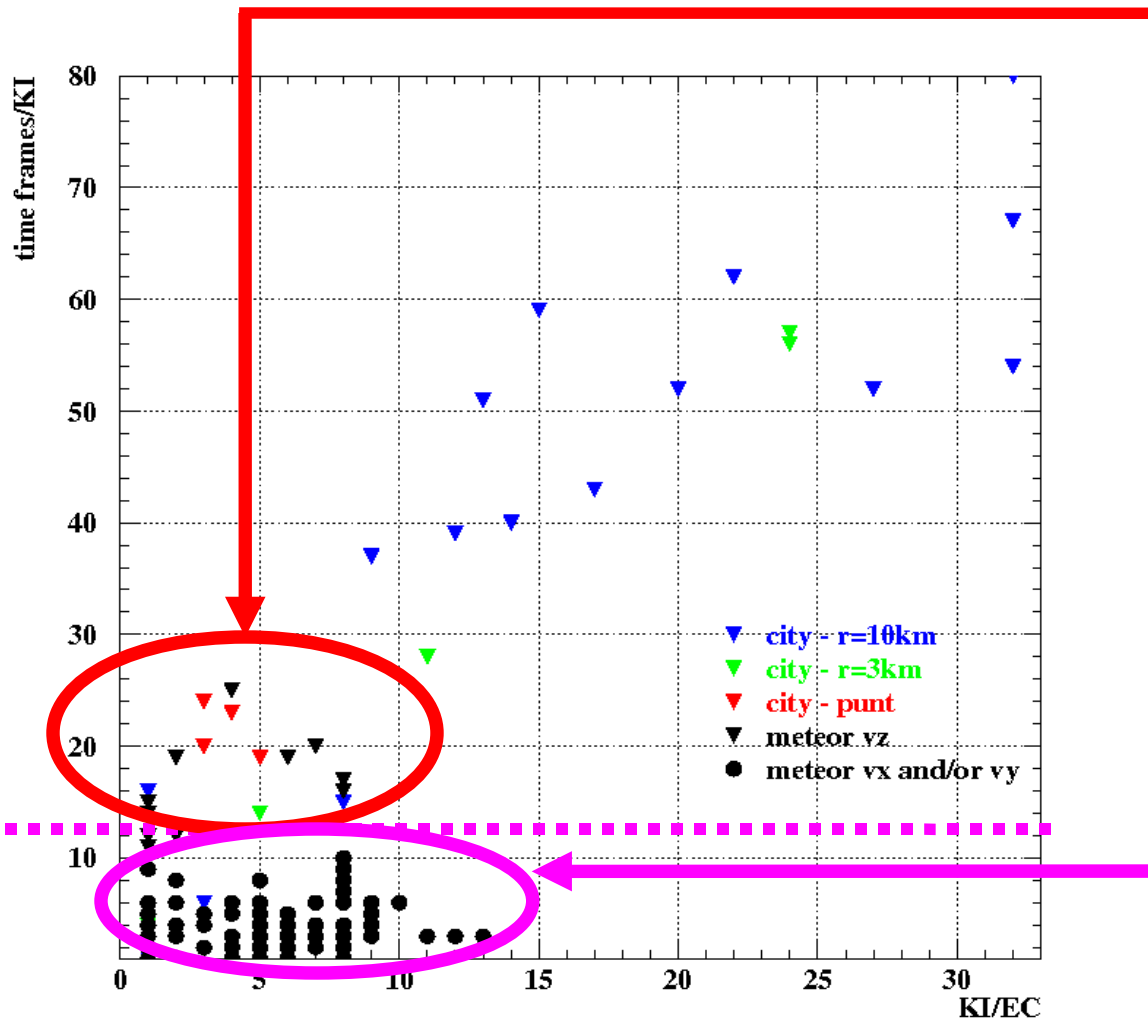

Vertical meteor

PDM size: 48 X 48 pixels

Cities vs meteors: criteria

Meteors with zenith angle $\theta < 45^\circ$ and villages look similar

Possible criteria to distinguish them :

- shape of the light curve
- number of enlightened PDMs
- threshold on the magnitude

Meteors with zenith angle $\theta > 45^\circ$ are easily detectable

1 EC = 32 KIs

Fireballs and HV protection logic

$$M < -13.5$$

number of events on Earth:
 $< 2 \cdot 10^{-3} / \text{day} \sim 0.73 / \text{year}$

Number of events on JEM-EUSO FoV at ground
(duty cycle 0.2):
 $< 5.4 \cdot 10^{-5} / \text{year}$

**HV switch-logic protects the telescope
from very luminous fireballs**

Conclusions

Main results:

- 1) **a simulator of meteors has been developed;**
- 2) **a simple simulator of the response of JEM – EUSO detector has been developed.**

By – products of the work:

- 1) **simulations of cities;**
- 2) **a first criterion to distinguish meteors from cities;**
- 3) **an analysis of the switch-logic that confirms its capability to protect the telescope from extremely bright objects such as fireballs.**

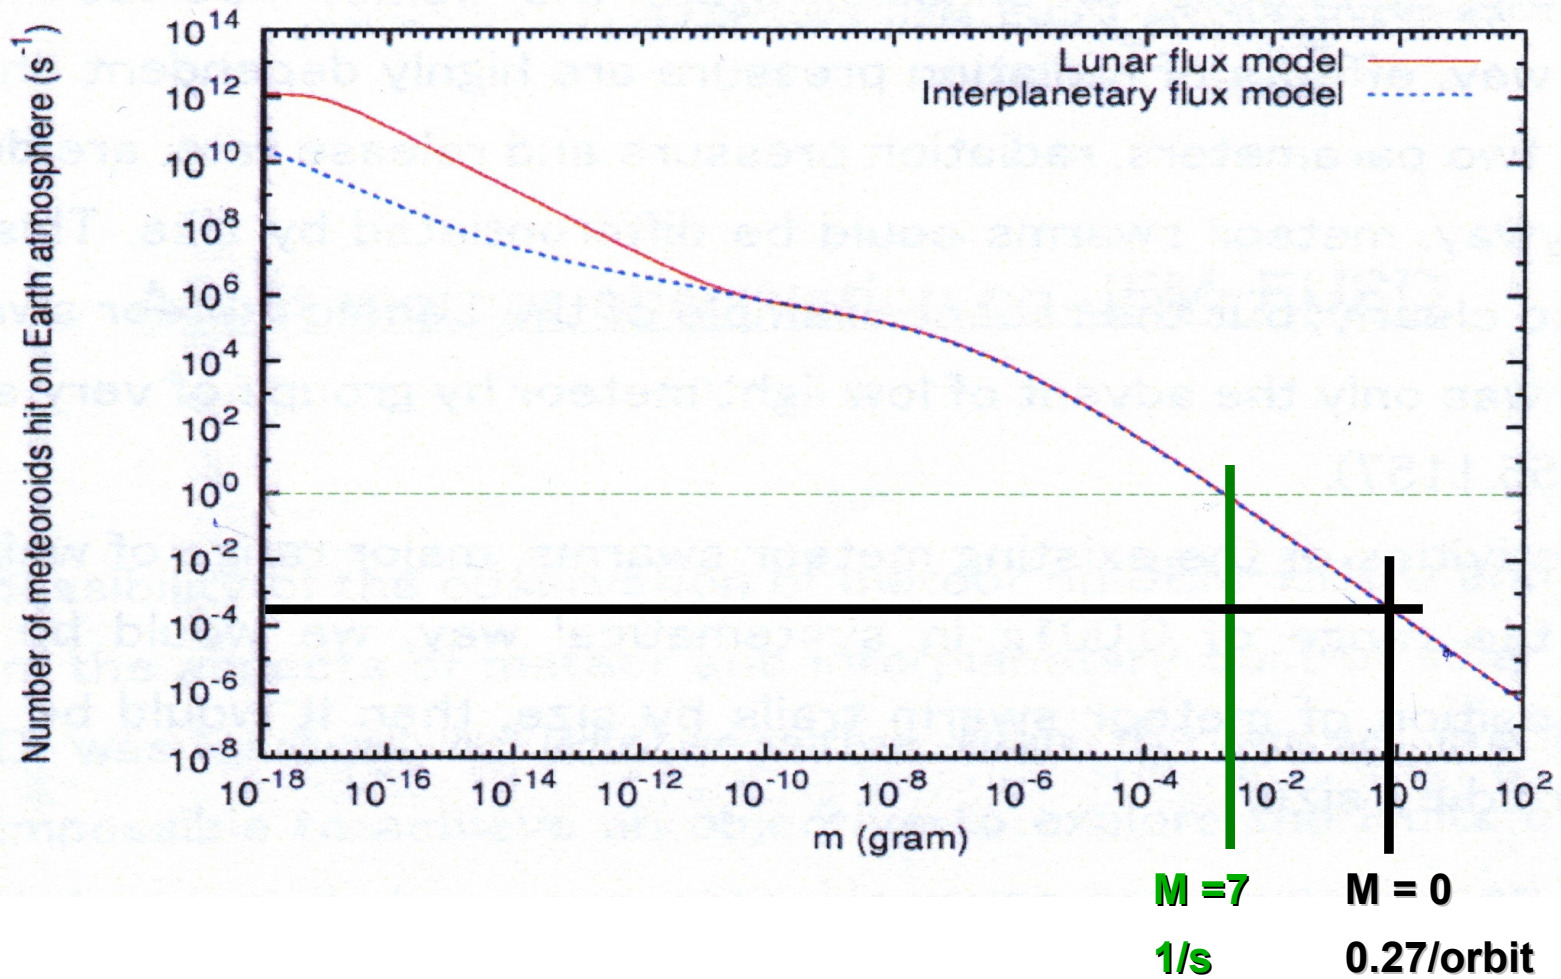

THANK YOU !!!
