Closing Remarks of NuMass 2022

Carlo Giunti

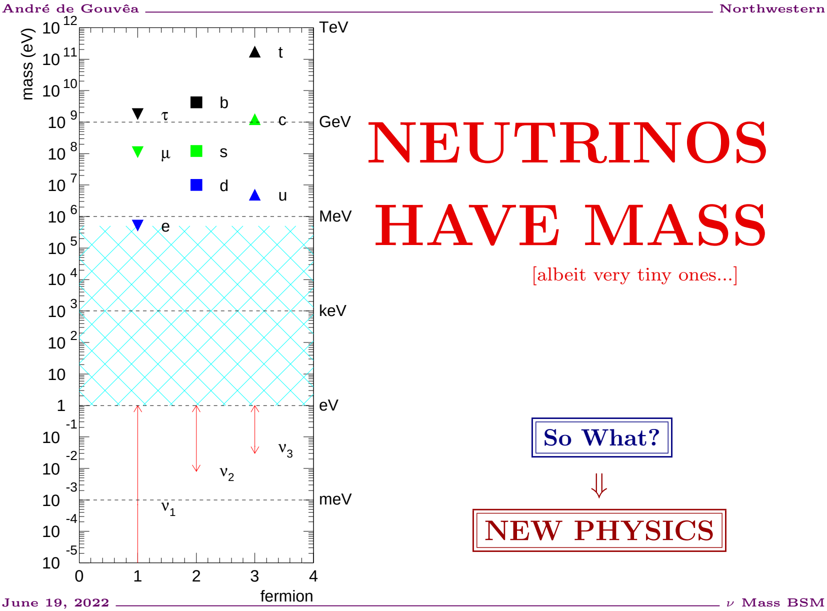
INFN, Torino, Italy

NuMass 2022
Determination of the Absolute Electron (Anti)-Neutrino Mass
6–10 June 2022

Caveats

- This is a summary of some topics presented and discussed in the workshop.
- The selection of the topics is based on my limited understanding.
- I apologize to the many presenters of wonderful technical achievements that I am not able to report.

Andre de Gouvea: Neutrino Mass: Beyond the Standard Model



André de Gouvêa — Northwestern

NEUTRINOS HAVE MASS

[albeit very tiny ones...]

So What?

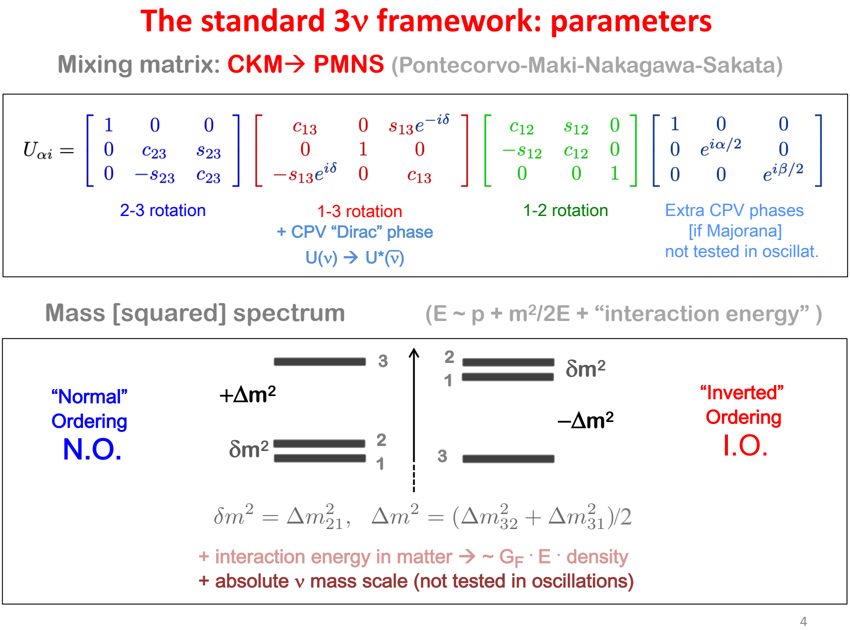
NEW PHYSICS

June 19, 2022 — ν Mass BSM

Eligio Lisi: Status of mass-mixing parameters in the three-neutrino framework



The standard 3ν framework: parameters

Mixing matrix: CKM→ PMNS (Pontecorvo-Maki-Nakagawa-Sakata)

$$U_{\alpha i} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & c_{23} & s_{23} \\ 0 & -s_{23} & c_{23} \end{bmatrix} \begin{bmatrix} c_{13} & 0 & s_{13}e^{-i\delta} \\ 0 & 1 & 0 \\ -s_{13}e^{i\delta} & 0 & c_{13} \end{bmatrix} \begin{bmatrix} c_{12} & s_{12} & 0 \\ -s_{12} & c_{12} & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & e^{i\alpha/2} & 0 \\ 0 & 0 & e^{i\beta/2} \end{bmatrix}$$

2-3 rotation

1-3 rotation
+ CPV “Dirac” phase
U(ν) → U*($\overline{\nu}$)

1-2 rotation

Extra CPV phases
[if Majorana]
not tested in oscillat.

Mass [squared] spectrum (E ~ p + m²/2E + “interaction energy”)

“Normal” Ordering
N.O.

“Inverted” Ordering
I.O.

$$\delta m^2 = \Delta m^2_{21}, \quad \Delta m^2 = (\Delta m^2_{32} + \Delta m^2_{31})/2$$

+ interaction energy in matter → ~ $G_F \cdot E \cdot$ density
+ absolute ν mass scale (not tested in oscillations)

4

Eligio Lisi: Status of mass-mixing parameters in the three-neutrino framework

Beautiful ν oscillation data have established this 3ν framework…

e→e (KamLAND, KL)

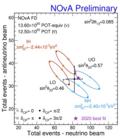
FIG. 4: Current best-fit values of the neutrino masses m_1, m_2, m_3 as a function of the lightest neutrino mass, for the normal mass-ordering (top) and the inverted mass ordering (bottom).

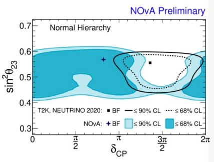
June 19, 2022 ν Mass BSM

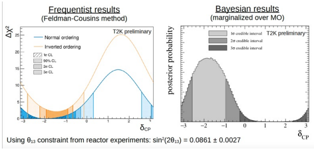
Eligio Lisi: Status of mass-mixing parameters in the three-neutrino framework

NO/IO and δ_{CP} overview

T2K and NOvA: still in tension; but no joint analysis yet. IC-DC: IO and δ not discussed yet.

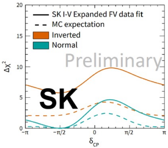


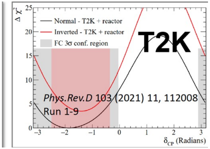




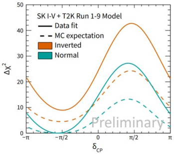
Using θ_{13} constraint from reactor experiments: $\sin^2(2\theta_{13}) = 0.0861 \pm 0.0027$

But SK atm. alone, and SK atm. +T2K → Increased preference for NO and for sinδ < 0





→ SK+T2K



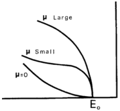
Comment #1: Seperately revised cross sections have not shed light on T2K vs NOvA tension
Comment #2: … but joint T2K+NOvA analysis with common interaction model still lacking
Comment #3: SK and T2K synergy strengthens current hints on NO/IO and δ_{CP}
Comment #4: … but SK speaker admits that *“Results from both experiments exceed sensitivity”*

Absolute neutrino mass: main focus of NuMass talks!

Including the last 3ν unknowns & their observables (m_β , $m_{\beta\beta}$, Σ)

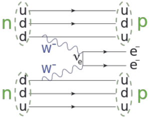
β decay, sensitive to the "effective electron neutrino mass":

$$m_\beta = \left[c_{13}^2 c_{12}^2 m_1^2 + c_{13}^2 s_{12}^2 m_2^2 + s_{13}^2 m_3^2\right]^{\frac{1}{2}}$$



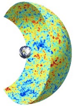
0νββ decay: only if Majorana. "Effective Majorana mass":

$$m_{\beta\beta} = \left|c_{13}^2 c_{12}^2 m_1 + c_{13}^2 s_{12}^2 m_2 e^{i\phi_2} + s_{13}^2 m_3 e^{i\phi_3}\right|$$



Cosmology: Dominantly sensitive to sum of neutrino masses:

$$\Sigma = m_1 + m_2 + m_3$$



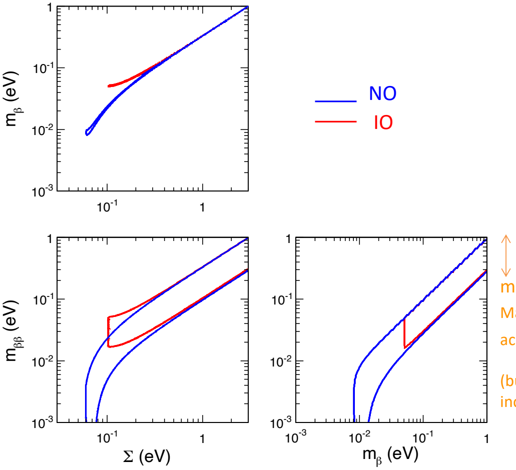
Note 1: These observables may provide handles to distinguish NO/IO.

Note 2: Majorana case gives a new source of CPV (unconstrained)

Note 2: The three observables are correlated by oscillation data→

Eligio Lisi: Status of mass-mixing parameters in the three-neutrino framework

Impact of oscillations on non-oscillation parameter space (2σ)

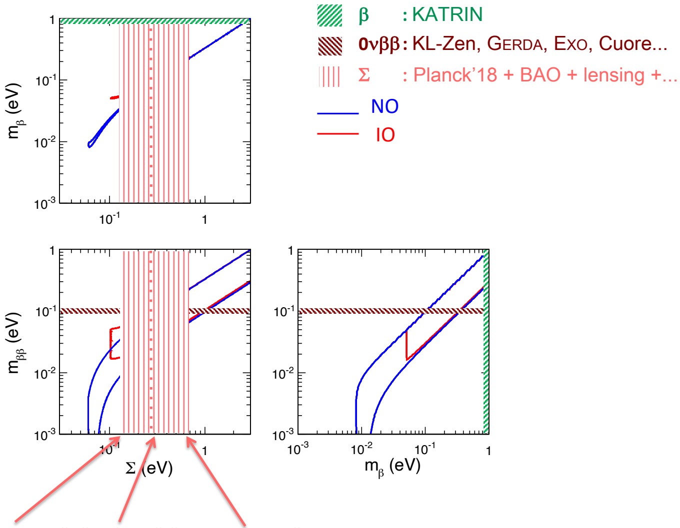


$m_{\beta\beta}$ spread due to Majorana CP phase(s): accessible in principle

(but: no NME errors included here!)

Eligio Lisi: Status of mass-mixing parameters in the three-neutrino framework

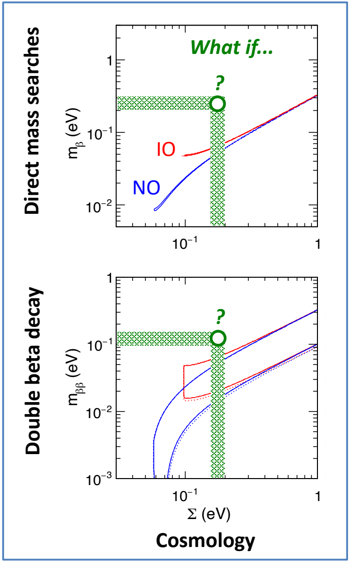
Cosmology: variety of upper bounds, with IO “under pressure”



“Aggressive” “Default” “Conservative” cosmological limits

Eligio Lisi: Status of mass-mixing parameters in the three-neutrino framework

Future data might also bring us beyond 3ν and re-shape the field...



Lack of convergence among data (barring expt mistakes) **might point towards new possibilities:**

- *Cosmology beyond ΛCDM*
- *Alternative DBD mechanisms*
- *New interactions (NSI)*
- *New neutrino states ...*

→ **See talks by: de Gouvea, Tyagi**

Main contender in current ν physics:
Light sterile ν at O(1 eV) scale
but... confusing/unconfirmed hints
→ **See talk by Ternes**

In any case: generic expectations
for new possible ν mass state(s)

Indirect probes of CνB

- Impact on power spectrum of matter density fluctuations

$$\delta_{\rm cdm}^{m_\nu=0} \propto a$$

$$\delta_{\rm cdm}^{m_\nu\neq 0} \propto a^{1-\frac{3}{5}\frac{\Omega_\nu}{\Omega_m}}$$

Planck TT,TE,EE + low E + lensing + BAO
$\Sigma m_\nu < 0.12$ eV (95%cl)

Planck TT,TE,EE + low E + lensing + BAO
+Lyman-α
$\Sigma m_\nu < 0.09$ (95%cl) [Palanque-Delabrouille et al. 2020]

Bounds on Σm_ν

95%CL upper bounds on $\Sigma_i m_i$ for 7 parameters

CMB temperature and polarisation from Planck
$\Sigma_i m_i < 260$ meV (95%CL)

CMB + conservative LSS information (BAO + RSD from BOSS):
$\Sigma_i m_i < 100$ meV (95%CL)

CMB + BAO + more agressive LSS:
either: + Ly-α from BOSS
or: + lensing + RSD + SNIa)
$\Sigma_i m_i < 87$ meV (95%CL)

Palanque-Delabrouille et al. 2020
Di Valentino et al. 2021

21 Neutrino mass and number from cosmology - J. Lesgourgues

- The bound $\sum_i m_i < 0.09\ \text{eV} \quad (95\%\ \text{C.L.})$ was obtained assuming $\sum_i m_i > 0$.

- An analysis adopting the oscillation prior $\sum_i m_i \gtrsim 0.05\ \text{eV}$ would return a looser bound.

- Thus, inverted hierarchy cannot be considered as disfavored at the 2σ level.

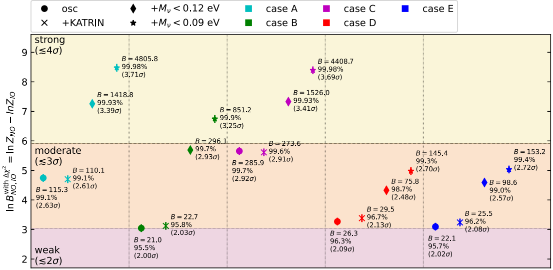
[Palanque-Delabrouille, Yeche, Schoneberg, Lesgourgues, Walther, Chabanier, Armengaud, arXiv:1911.09073]

Maria Archidiacono: What cosmology can tell us about neutrinos

The debate over the hierarchy

Degenerate hierarchy (DH) approximation: $m_1 = m_2 = m_3$

«Moderate evidence, mostly driven by neutrino oscillation data» Gariazzo et al. 2022 (see also Hergt et al. 2021)



<u>case A</u> is based on Jimenez et al.: a Gaussian prior on the logarithm of the three neutrino mass eigenstates

"The significance of the preference in favor of NO changes significantly when we consider different parameterizations."

For a different approach, Long et al. 2018, and Heavens & Sellentin 2018

Maria Archidiacono – University of Milan

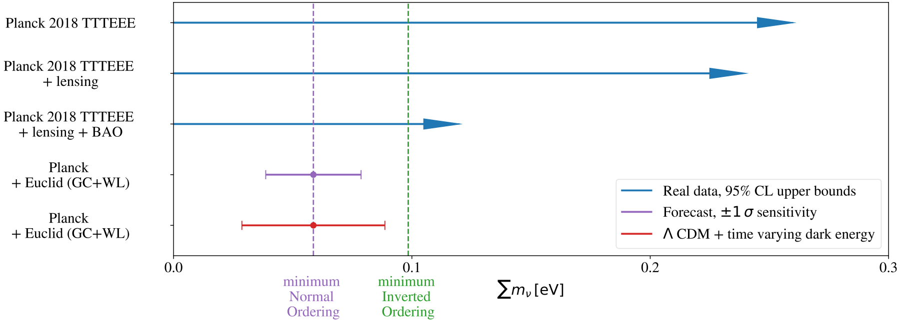
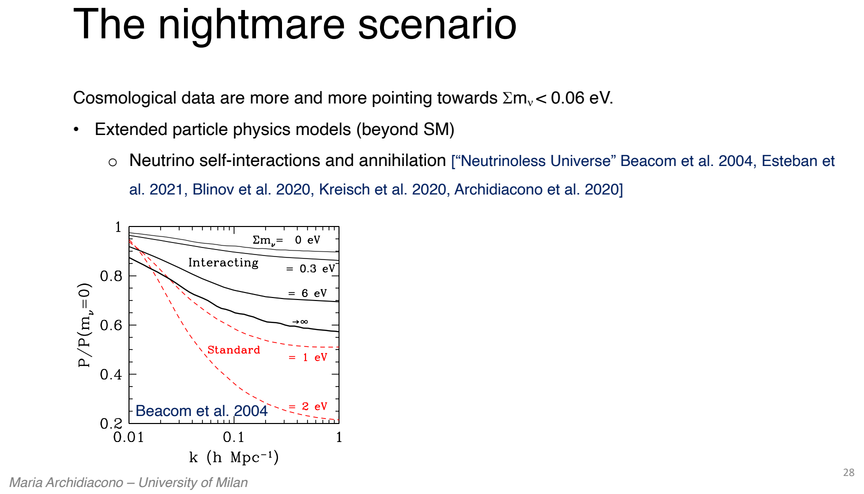
Neutrino mass constraints: the future



Maria Archidiacono: What cosmology can tell us about neutrinos



The nightmare scenario

Cosmological data are more and more pointing towards $\Sigma m_\nu < 0.06$ eV.

- Extended particle physics models (beyond SM)
  - Neutrino self-interactions and annihilation ["Neutrinoless Universe" Beacom et al. 2004, Esteban et al. 2021, Blinov et al. 2020, Kreisch et al. 2020, Archidiacono et al. 2020]

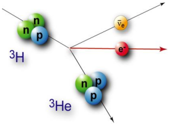
Maria Archidiacono – University of Milan

28

The interesting (exciting) scenario!

Direct Neutrino Mass Measurement with Beta Decay

Use Kinematics only, look at the end-point shape



$$\frac{dN}{dE_e} = C \cdot F(E,Z) \cdot P_e \cdot (E_e + m_e c^2) \cdot (E_o - E_e)\sqrt{(E_o - E_e)^2 - m_{\nu_e}{}^2}$$

(some details/corrections not included)

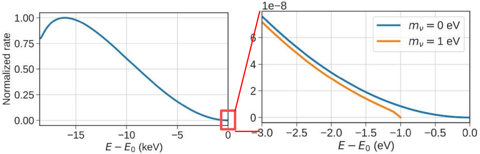
$$\sum_i |U_{ei}|^2 \cdot m_i{}^2 \sim m_i{}^2$$

in degenerated region

$$^3\mathrm{H} \rightarrow {}^3\mathrm{He} + \mathrm{e}^- + \bar{\nu}_\mathrm{e}$$

Tritium as beta-source

- low end-point (18.6 keV)
  - → relatively large deformation
  - → electro-statically reachable
- short life (12.3 y):
  - → small source amount
  - → less scattering in source
- super-allowed transition
  - → matrix element reliably calculable
- simplest molecular:
  - → molecular states calculable



only 2×10^{-13} of all beta in last 1 eV

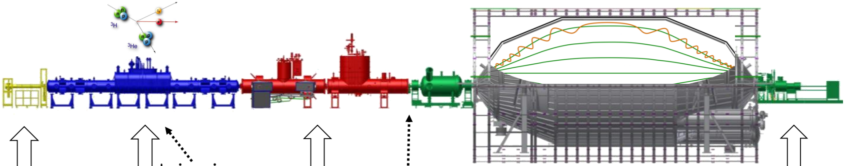
Needs:

- strong stable source
- high precision spectroscopy

KATRIN Experiment (Design)

KArlsruhe TRItium Neutrino Experiment

- located at Karlsruhe Institute of Technology, Karlsruhe, Germany
- design sensitivity: $m(\nu_e) < 0.2$ eV (90%CL, 3 years)



Calibration
e-Gun

Injection
1.8 mbar l/s

10^{-14} mbar l/s

10^{-11} mbar

Tritium Retention
(electrons guided by B)

Electron Counter
(~10 mHz)

100 GBq Gaseous Tritium Source
(largest ever tritium throughput, as of 2018)

0.9 eV Resolution MAC-E Filter
(largest ever UHV vessel, as of 2013)

All numbers are from KATRIN Design Report (2004)

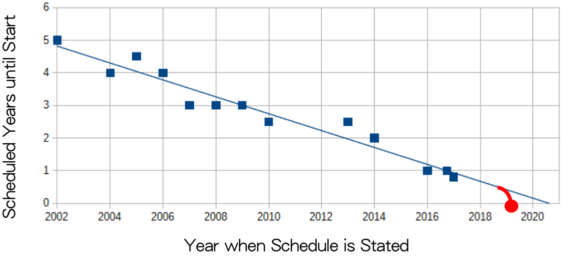
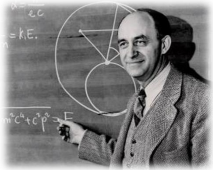
KATRIN Construction History

- First Collaboration Meeting in 2001
- Design Report in 2004, planned to start in 4 years
- Strat data taking in 2019





Versuch einer Theorie der β-Strahlen. I[1]).

Von **E. Fermi** in Rom.

Mit 3 Abbildungen. (Eingegangen am 16. Januar 1934.)

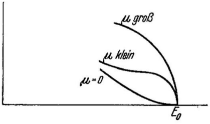


Fig. 1.

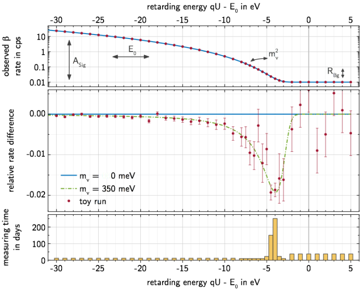
KATRIN has demonstrated end-points are deformed!!

and that there can be one correct red point
in a plot with many wrong blue points

Neutrino Mass Analysis and Results

Spectrum Model and Measurement Strategy

(MC made before measurements)



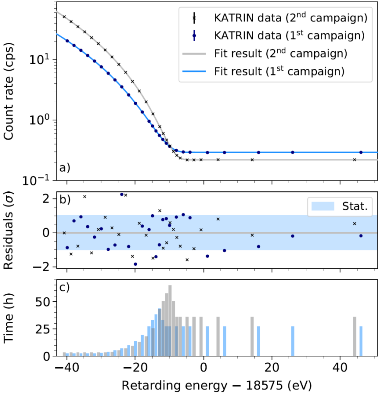
$$\underbrace{N(qU)}_{\text{retarding energy}} = A \cdot \int_{qU}^{E_0} \underbrace{\frac{d\Gamma}{dE}(E; m_\nu^2, E_0)}_{\text{beta decay spectrum}} \cdot \underbrace{f(qU,E)}_{\text{apparatus response}}\, dE + B$$

activity

backgrounds

plus a number of nuisance parameters

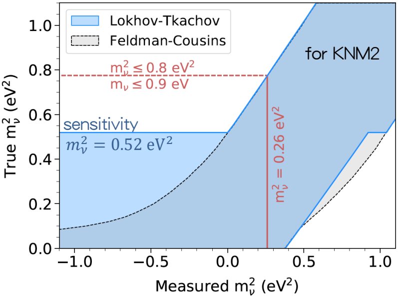
Measured Spectra and Fitting Results



$$\boxed{m_\nu^2 = 0.26 \pm 0.34\ \text{eV}^2}$$

Sanshiro Enomoto: KATRIN neutrino mass analysis and results

Mass Limit Setting



Feldman-Cousins (FC)

- De facto standard
- Provided only for supplementary

Lokhov-Tkachov (LT)

- No “tighter limit” from negative m^2
- For negative m^2, stop at the sensitivity
- Coverage is still correct (no flip-flopping)

A. Lokhov is in this meeting!

KNM 1

$m_\nu^2 = -1.0^{+0.9}_{-1.1}$ eV^2

$m_\nu < 1.1$ eV (LT 90%CL)

($m_\nu < 0.8$ eV (FC 90%CL))

KNM 2

$m_\nu^2 = 0.26 \pm 0.34$ eV^2

$m_\nu < 0.9$ eV (90%CL)

KNM 1 & 2 combined

$m_\nu^2 = 0.1 \pm 0.3$ eV^2

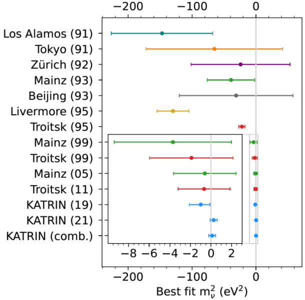
$m_\nu < 0.8$ eV (90%CL)

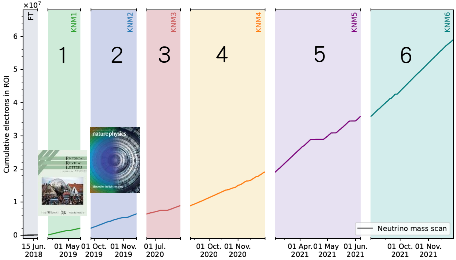
Independent Consistency Check: Beta-decay Q-value

KATRIN:	18575.20 ± 0.60 eV
Δm (^{3}He - ^{3}H):	18575.72 ± 0.07 eV (this information is not used for spectrum fitting)

Conclusions and Outlook

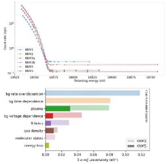
- First sub-eV result: $m_\nu^2 = 0.1 \pm 0.3\ \mathrm{eV}^2,\ m_\nu < 0.8$ eV (90%CL)
- Final design sensitivity 0.2 eV (90%CL) in 5 years





Run 7 is on-going

- Much more data already in hand, being analyzed (still blinded)
- After KNM 2: BG have been significantly reduced
- After KNM 2: Systematics have been significantly reduced



Preliminary estimated sensitivity up to KNM 5: <0.5 eV (90%CL)
Unblinding of KNM 3-5 is planned in this summer

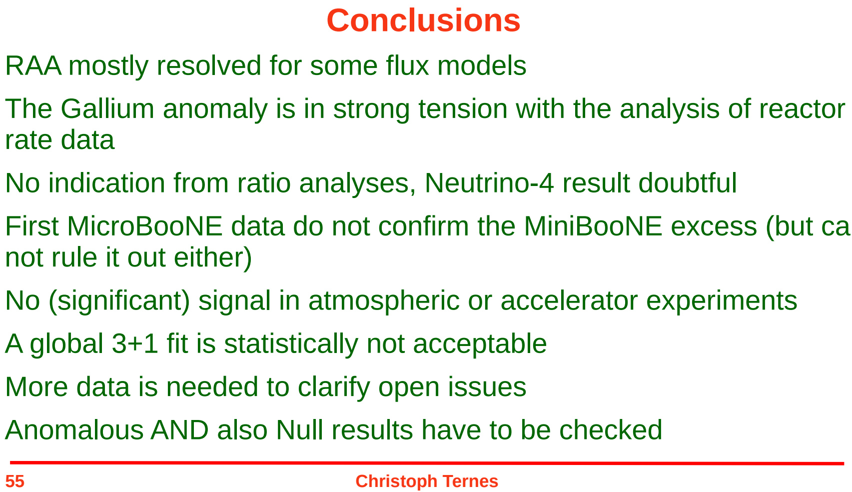
"Spaceship KATRIN"

6 08.06.2022 Alexey Lokhov – KATRIN beyond the neutrino mass Institute of experimental particle physics

Christoph Ternes: Current status of 3+1 neutrino mixing



Conclusions

RAA mostly resolved for some flux models

The Gallium anomaly is in strong tension with the analysis of reactor rate data

No indication from ratio analyses, Neutrino-4 result doubtful

First MicroBooNE data do not confirm the MiniBooNE excess (but can not rule it out either)

No (significant) signal in atmospheric or accelerator experiments

A global 3+1 fit is statistically not acceptable

More data is needed to clarify open issues

Anomalous AND also Null results have to be checked

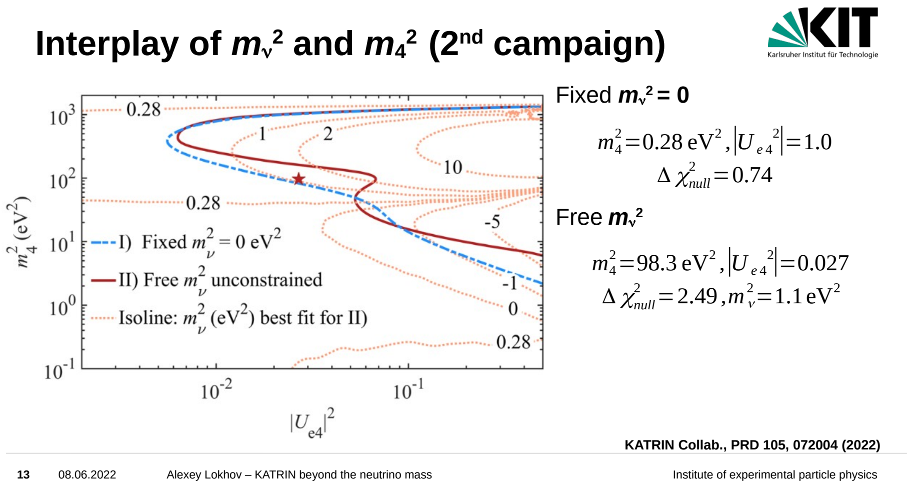
- 3+1 sterile neutrino model
- Same data-set as for the neutrino mass
- Grid search in m_4, $|U_{e4}|^2$ plane

$$\frac{d\Gamma}{dE} = \underbrace{\left(1-|U_{e4}|^2\right)\frac{d\Gamma}{dE}(m_\beta^2)}_{\text{light neutrino}} + \underbrace{|U_{e4}|^2\,\frac{d\Gamma}{dE}(m_4^2)}_{\text{heavy neutrino}}$$

8 08.06.2022 Alexey Lokhov – KATRIN beyond the neutrino mass Institute of experimental particle physics

Alexey Lokhov: KATRIN beyond the neutrino mass measurements



Interplay of m_ν^2 and m_4^2 (2nd campaign)

Fixed $m_\nu^2 = 0$

$$m_4^2 = 0.28\,\text{eV}^2, |U_{e4}^2| = 1.0$$

$$\Delta\chi^2_{null} = 0.74$$

Free m_ν^2

$$m_4^2 = 98.3\,\text{eV}^2, |U_{e4}^2| = 0.027$$

$$\Delta\chi^2_{null} = 2.49, m_\nu^2 = 1.1\,\text{eV}^2$$

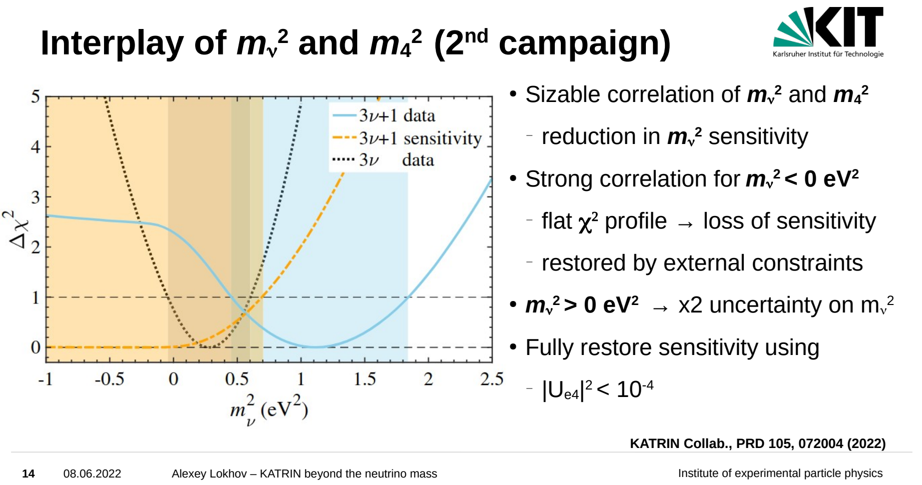
KATRIN Collab., PRD 105, 072004 (2022)

13 08.06.2022 Alexey Lokhov – KATRIN beyond the neutrino mass Institute of experimental particle physics

Please try to find the bound for free m_ν:

- In the $|U_{e4}|^2$–Δm^2_{SBL} plane, with $\Delta m^2_{\text{SBL}} = m_4^2 - m_\nu^2$ and $m_4^2 > m_\nu^2$.
- Considering only positive m_ν^2.

Alexey Lokhov: KATRIN beyond the neutrino mass measurements



Interplay of m_ν^2 and m_4^2 (2nd campaign)

- Sizable correlation of m_ν^2 and m_4^2
  - reduction in m_ν^2 sensitivity
- Strong correlation for $m_\nu^2 < 0$ eV^2
  - flat χ^2 profile → loss of sensitivity
  - restored by external constraints
- $m_\nu^2 > 0$ eV^2 → x2 uncertainty on m_ν^2
- Fully restore sensitivity using
  - $|U_{e4}|^2 < 10^{-4}$

KATRIN Collab., PRD 105, 072004 (2022)

$$m_\nu \lesssim \sqrt{2.3\ \text{eV}^2} \simeq 1.5\ \text{eV} \quad (90\%\ \text{C.L.}) \quad \text{in } 3\nu{+}1$$

about 1.7 times larger than $m_\nu \lesssim \sqrt{0.8\ \text{eV}^2} \simeq 0.9$ eV (90% C.L.) in 3ν !

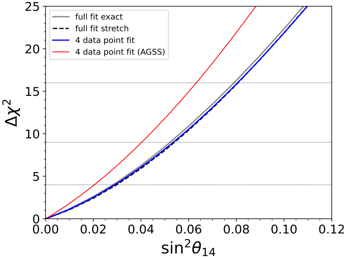
- I think that the interpretation depends on the values of $|U_{e4}|^2$ corresponding to the marginalized $\Delta\chi^2$ curve.
- The sensitivity to m_ν obviously decreases for increasing $|U_{e4}|^2$, because

$$\frac{d\Gamma}{dE} = \left(1 - |U_{e4}|^2\right) \frac{d\Gamma}{dE}(m_\nu) + |U_{e4}|^2 \frac{d\Gamma}{dE}(m_4)$$

- A reliable bound on $|U_{e4}|^2$ is the solar neutrino limit:

[Goldhagen, Maltoni, Reichard, Schwetz, arXiv:2109.14898]

$$\sin^2\theta_{14} = |U_{e4}|^2$$



- I think that it would be useful to see:
  - The $\Delta\chi^2$ contours in the m_ν–$|U_{e4}|^2$ plane.
  - The $\Delta\chi^2$ for m_ν with a solar $\Delta\chi^2$ pull term.

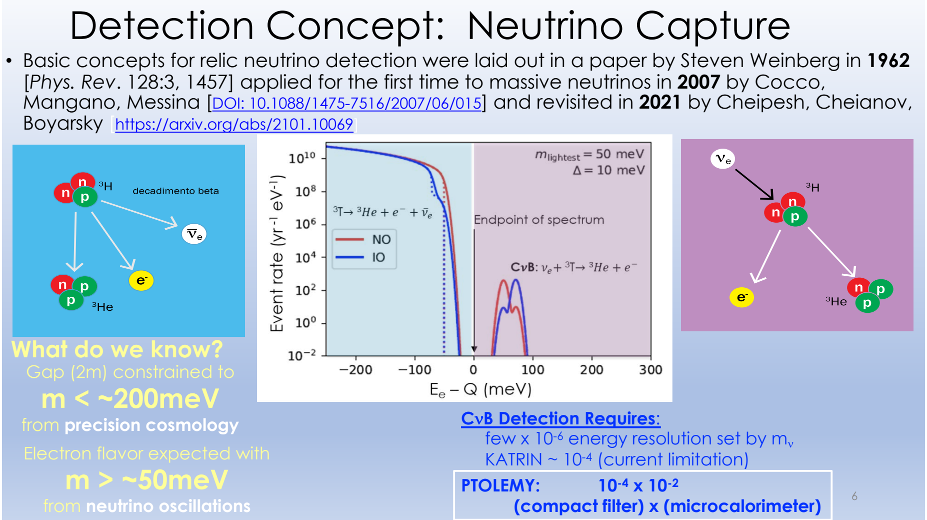
= 0.17 meV (0.17 meV/100 meV)
= 0.3 μeV

Ultra-Cold!

Chris Tully: Status of PTOLEMY



Detection Concept: Neutrino Capture

- Basic concepts for relic neutrino detection were laid out in a paper by Steven Weinberg in **1962** [*Phys. Rev.* 128:3, 1457] applied for the first time to massive neutrinos in **2007** by Cocco, Mangano, Messina [DOI: 10.1088/1475-7516/2007/06/015] and revisited in **2021** by Cheipesh, Cheianov, Boyarsky https://arxiv.org/abs/2101.10069

What do we know?

Gap (2m) constrained to

m < ~200meV

from **precision cosmology**

Electron flavor expected with

m > ~50meV

from **neutrino oscillations**

CνB Detection Requires:

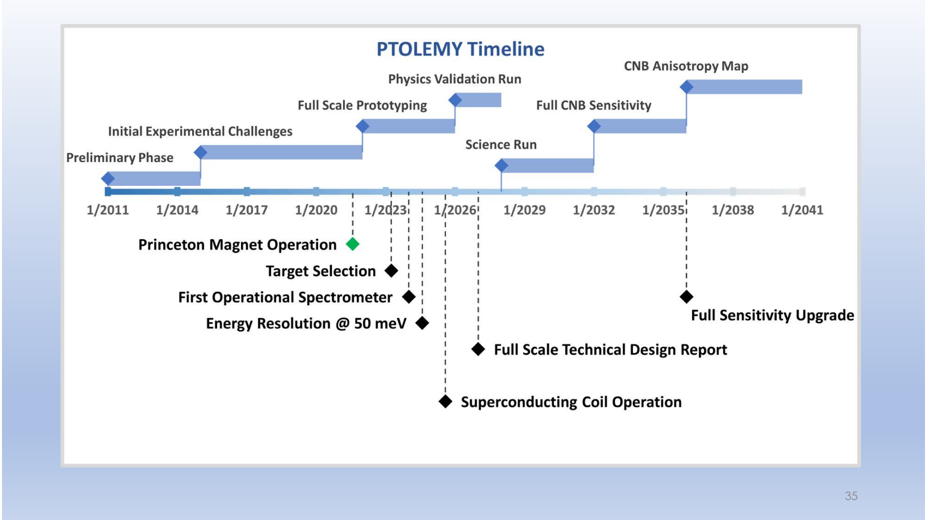
few x 10^{-6} energy resolution set by m_ν

KATRIN ~ 10^{-4} (current limitation)

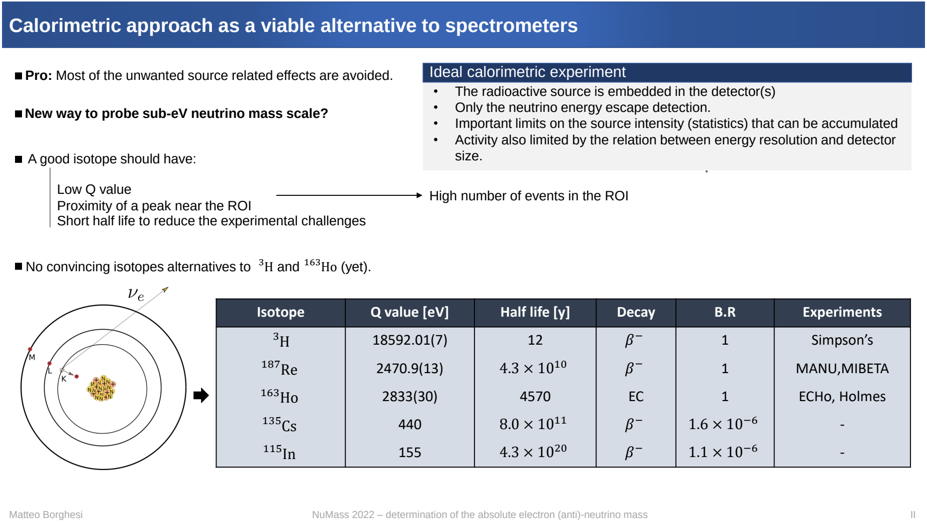
PTOLEMY: **10^{-4} x 10^{-2}**

(compact filter) x (microcalorimeter)

Chris Tully: Status of PTOLEMY



Matteo Borghesi: An updated overview of the HOLMES status



Calorimetric approach as a viable alternative to spectrometers

- **Pro:** Most of the unwanted source related effects are avoided.
- **New way to probe sub-eV neutrino mass scale?**
- A good isotope should have:

  Low Q value
  Proximity of a peak near the ROI
  Short half life to reduce the experimental challenges

  → High number of events in the ROI

Ideal calorimetric experiment

- The radioactive source is embedded in the detector(s)
- Only the neutrino energy escape detection.
- Important limits on the source intensity (statistics) that can be accumulated
- Activity also limited by the relation between energy resolution and detector size.

- No convincing isotopes alternatives to $^{3}\mathrm{H}$ and $^{163}\mathrm{Ho}$ (yet).

Isotope	Q value [eV]	Half life [y]	Decay	B.R	Experiments
$^{3}\mathrm{H}$	18592.01(7)	12	β^-	1	Simpson's
$^{187}\mathrm{Re}$	2470.9(13)	4.3×10^{10}	β^-	1	MANU,MIBETA
$^{163}\mathrm{Ho}$	2833(30)	4570	EC	1	ECHo, Holmes

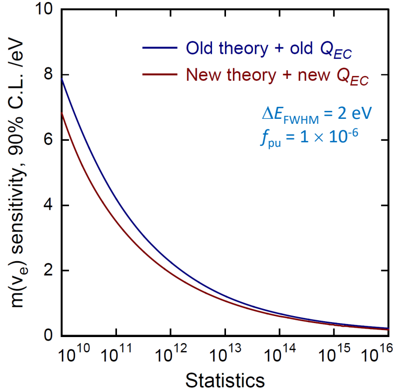
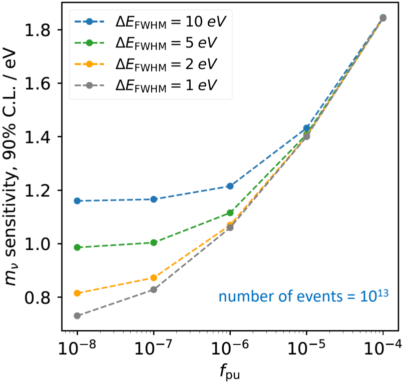
Updated sensitivity

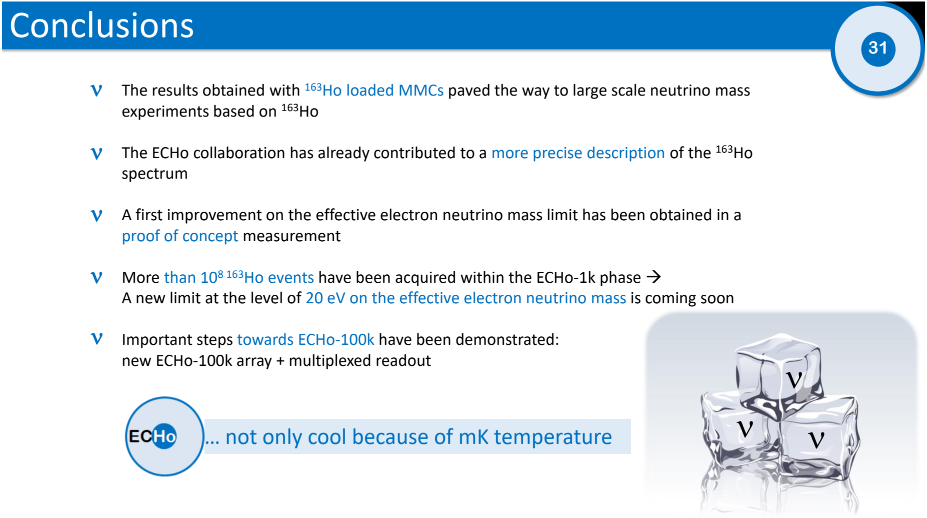
Brass & Haverkort theoretical model + new Q_{EC}-value



Sensitivity for the coming phase of ECHo



Loredana Gastaldo: Report on ECHo activities and results



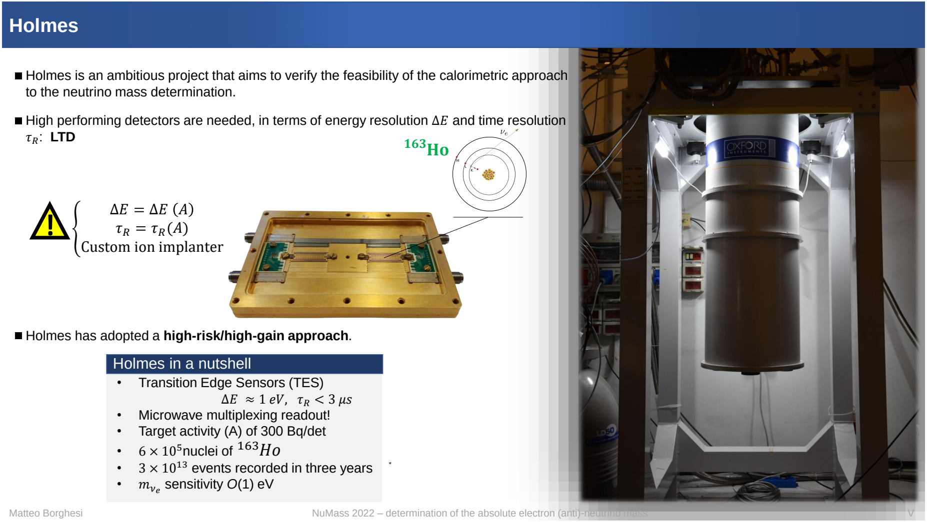
Conclusions

31

- ν The results obtained with ^{163}Ho loaded MMCs paved the way to large scale neutrino mass experiments based on ^{163}Ho
- ν The ECHo collaboration has already contributed to a more precise description of the ^{163}Ho spectrum
- ν A first improvement on the effective electron neutrino mass limit has been obtained in a proof of concept measurement
- ν More than 10^8 ^{163}Ho events have been acquired within the ECHo-1k phase → A new limit at the level of 20 eV on the effective electron neutrino mass is coming soon
- ν Important steps towards ECHo-100k have been demonstrated: new ECHo-100k array + multiplexed readout

ECHo … not only cool because of mK temperature

Matteo Borghesi: An updated overview of the HOLMES status



Holmes

- Holmes is an ambitious project that aims to verify the feasibility of the calorimetric approach to the neutrino mass determination.
- High performing detectors are needed, in terms of energy resolution ΔE and time resolution τ_R: **LTD**

$$\begin{cases} \Delta E = \Delta E\,(A) \\ \tau_R = \tau_R(A) \\ \text{Custom ion implanter} \end{cases}$$

- Holmes has adopted a **high-risk/high-gain approach**.

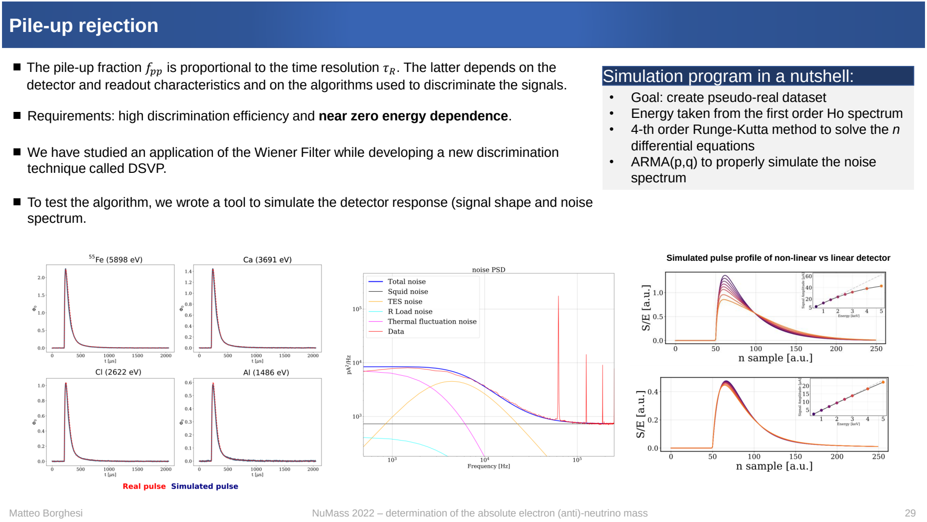
Holmes in a nutshell

- Transition Edge Sensors (TES)
  $\Delta E \approx 1\ eV,\ \ \tau_R < 3\ \mu s$
- Microwave multiplexing readout!
- Target activity (A) of 300 Bq/det
- 6×10^5nuclei of ^{163}Ho
- 3×10^{13} events recorded in three years
- m_{ν_e} sensitivity O(1) eV

Matteo Borghesi

NuMass 2022 – determination of the absolute electron (anti)-neutrino mass

Matteo Borghesi: An updated overview of the HOLMES status



Pile-up rejection

- The pile-up fraction f_{pp} is proportional to the time resolution τ_R. The latter depends on the detector and readout characteristics and on the algorithms used to discriminate the signals.
- Requirements: high discrimination efficiency and **near zero energy dependence**.
- We have studied an application of the Wiener Filter while developing a new discrimination technique called DSVP.
- To test the algorithm, we wrote a tool to simulate the detector response (signal shape and noise spectrum).

Simulation program in a nutshell:

- Goal: create pseudo-real dataset
- Energy taken from the first order Ho spectrum
- 4-th order Runge-Kutta method to solve the *n* differential equations
- ARMA(p,q) to properly simulate the noise spectrum

Real pulse **Simulated pulse**

Matteo Borghesi: An updated overview of the HOLMES status

Conclusions

- Tested and tuned the final array fabrication processes.

  These did not spoil the detectors' performances.

- The software for analysis and signal processing of microcalorimeters events is up and running!

- The expected background contributions were assessed, both with simulations and dedicate measurements.

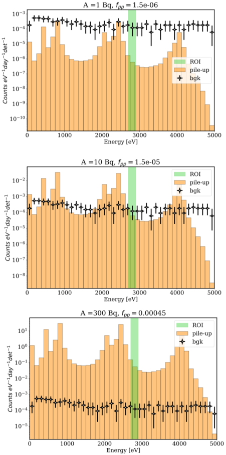
  A further reduction of a factor roughly 25% could be achieved with a similar setup studied in this work (muon veto).

  Pile-up reduction results equivalent to increase the measurement time by a factor 4: from 3 to 12 years.

- Ion implanter is working as expected. The production of a proper sputter target is almost ready!

- The first phase of the HOLMES experiment is expected on the last quarter of 2022: a low dose implantation of a 2×32 pixel array.
  - Influence of the Ho on the detector response will be assessed
  - A high resolution Ho calorimetric spectrum will help to discriminate between the different theoretical models
  - A first limit on the neutrino mass $O(10)$ eV will be reached

- These results will contribute to clarify if the calorimetric approach can still be considered a feasible way to reach the required sub-eV sensitivity on the neutrino mass.



Matteo Borghesi NuMass 2022 – determination of the absolute electron (anti)-neutrino mass

Oliviero Cremonesi: Review on neutrino-less double beta decay

Double beta decay (DBD)

Rare nuclear decay between isobars with |ΔQ|=2

Even-even nuclei: favorable experimental condition

Decay modes:

- (A,Z) → (A,Z+2) + 2e− + 2$\overline{\nu}$ (2νββ)
  - 2nd order transition (Standard Model)
  - Very long half-lives ($10^{18\text{-}24}$ yr)
- **(A,Z) → (A,Z+2) + $2e^-$ (0νββ)**
  - Lepton number violation (LNV): BSM physics

Possible ONLY IF neutrinos are Majorana fermions

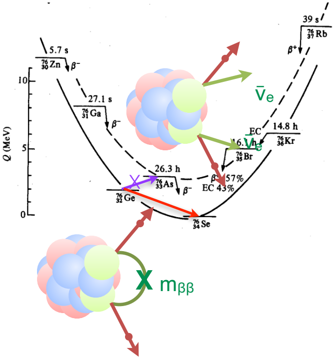
→ LNV (ΔL=2, B-L violation)

→ absolute neutrino mass scale

→ Majorana phases

SM estensions

- (A,Z) → (A,Z+2) + 2e- + exotics (e.g. nχ)



Oliviero Cremonesi - 08/06/2022 - NUMASS 2022

Oliviero Cremonesi: Review on neutrino-less double beta decay

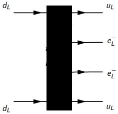
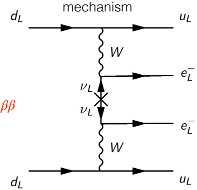
Lepton Number Violation (LNV) and *0νββ*



- A simple 'black box' with lots of possible modeling
- Great interest in the possibility of probing new physics

Mass mechanism



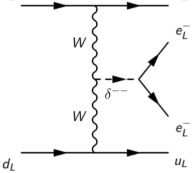
$A_{\beta\beta} \sim m_{\beta\beta}$

- Possibility of interference

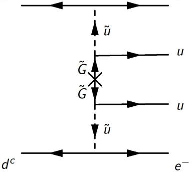
$$T_{1/2}^{-1} = G_\nu \left| \frac{m_{ee}}{m_e} M_\nu + \epsilon M_\epsilon \right|^2$$

➡ measurements on different isotopes

Higgs Triplet

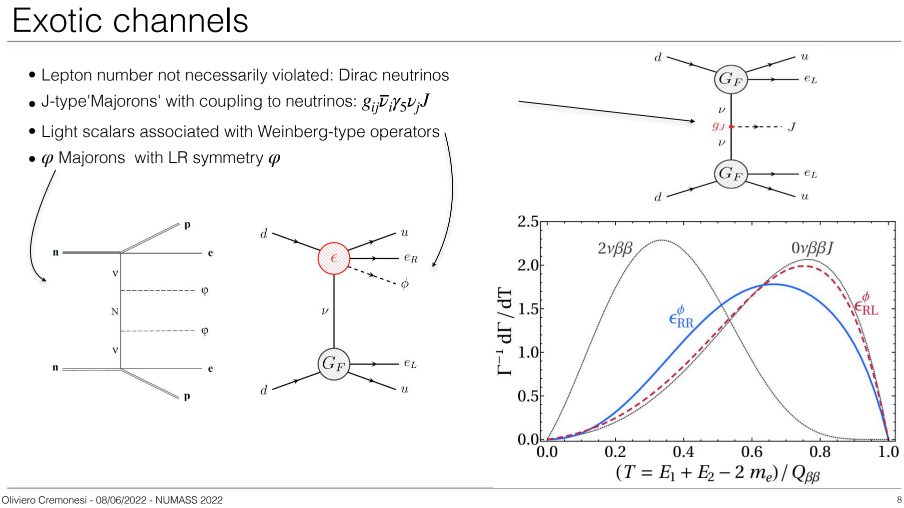


Supersimmetry



$A_{\beta\beta} \sim$ LNV parameters

Oliviero Cremonesi: Review on neutrino-less double beta decay



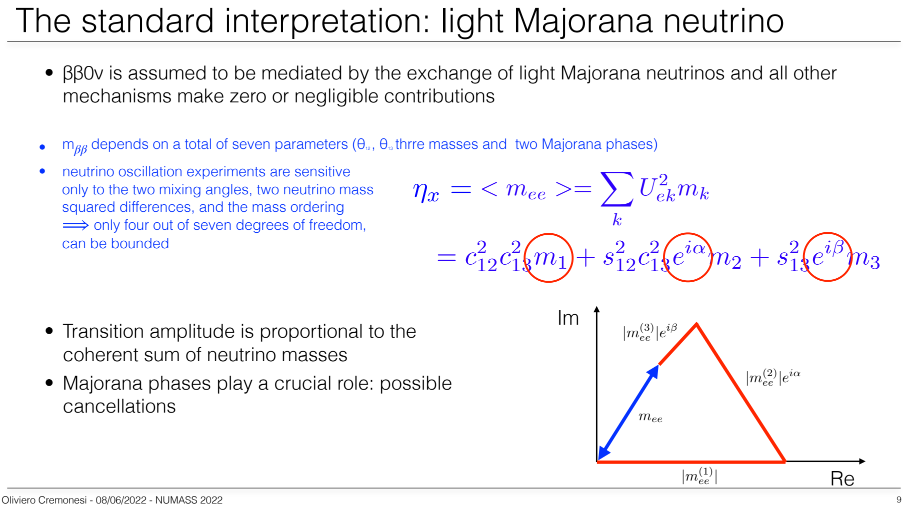
Exotic channels

- Lepton number not necessarily violated: Dirac neutrinos
- J-type'Majorons' with coupling to neutrinos: $g_{ij}\overline{\nu}_i\gamma_5\nu_j J$
- Light scalars associated with Weinberg-type operators
- φ Majorons with LR symmetry φ

Oliviero Cremonesi - 08/06/2022 - NUMASS 2022

8

Oliviero Cremonesi: Review on neutrino-less double beta decay



The standard interpretation: light Majorana neutrino

- ββ0ν is assumed to be mediated by the exchange of light Majorana neutrinos and all other mechanisms make zero or negligible contributions

- $m_{\beta\beta}$ depends on a total of seven parameters (θ_{12}, θ_{13} thrre masses and two Majorana phases)
- neutrino oscillation experiments are sensitive only to the two mixing angles, two neutrino mass squared differences, and the mass ordering $\Longrightarrow$ only four out of seven degrees of freedom, can be bounded

$$\eta_x = < m_{ee} > = \sum_k U_{ek}^2 m_k$$

$$= c_{12}^2 c_{13}^2 m_1 + s_{12}^2 c_{13}^2 e^{i\alpha} m_2 + s_{13}^2 e^{i\beta} m_3$$

- Transition amplitude is proportional to the coherent sum of neutrino masses
- Majorana phases play a crucial role: possible cancellations

Oliviero Cremonesi: Review on neutrino-less double beta decay

Light Majorana neutrinos

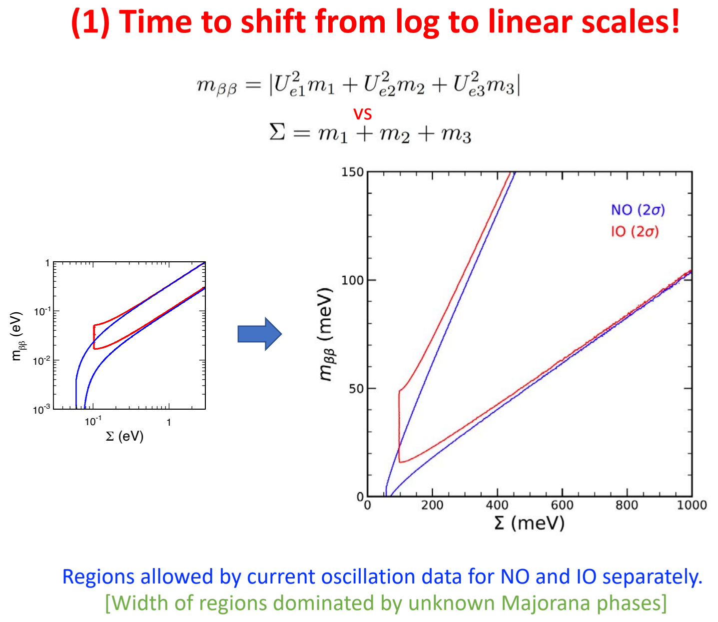
13

Eligio Lisi: Round Table: Discussion on Future



(1) Time to shift from log to linear scales!

$$m_{\beta\beta} = |U_{e1}^2 m_1 + U_{e2}^2 m_2 + U_{e3}^2 m_3|$$

vs

$$\Sigma = m_1 + m_2 + m_3$$

Regions allowed by current oscillation data for NO and IO separately.

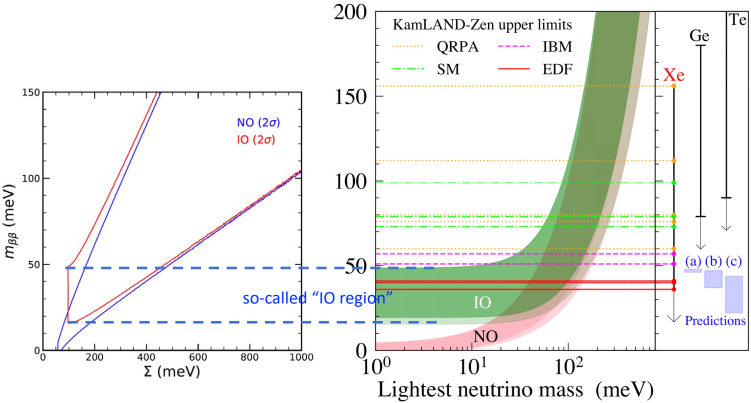
[Width of regions dominated by unknown Majorana phases]

Similarly for m_β vs Σ, without Majorana phase uncertainties

Eligio Lisi: Round Table: Discussion on Future

(2) Language bonus: avoid log-inspired misleading jargon

The (improperly named) "IO region" is compatible with NO as well…

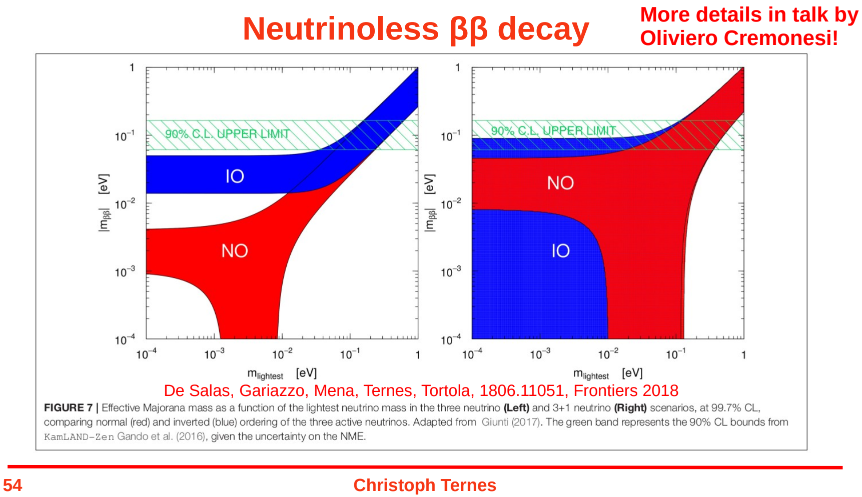


Important to note that Σ is observable while m_{lightest} is not.

Elongated stripes in $\log(m_{\text{lightest}})$ have no real significance.

Stat. bonus: If Bayesian results depend sensitively on log vs linear priors etc. → unreliable, IMHO

Christoph Ternes: Current status of 3+1 neutrino mixing



Neutrinoless ββ decay

More details in talk by Oliviero Cremonesi!

De Salas, Gariazzo, Mena, Ternes, Tortola, 1806.11051, Frontiers 2018

FIGURE 7 | Effective Majorana mass as a function of the lightest neutrino mass in the three neutrino **(Left)** and 3+1 neutrino **(Right)** scenarios, at 99.7% CL, comparing normal (red) and inverted (blue) ordering of the three active neutrinos. Adapted from Giunti (2017). The green band represents the 90% CL bounds from `KamLAND-Zen` Gando et al. (2016), given the uncertainty on the NME.

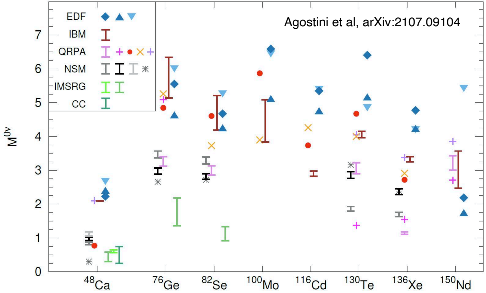
$m_{\beta\beta}$ extraction from data: a hard task

$M^{0\nu}$ values estimated from different calculation methods

$$\Gamma^{0\nu} = G_{0\nu}(Q,Z)|M_{0\nu}(A,Z)|^2|m_{ee}|^2$$

- Factor 2-3 "uncertainty" among nuclear models.
- 'Ab initio' calculations for lighter isotopes give lower values

NME calculations:
- EDF: large
- QRPA: larger spread
- NSM: small
- IMSRG ^{48}Ca ab initio: very small



Much more problematic: nuclear matrix elements

- Significant differences
- Results inaccuracy

g_A quenching?

Jouni Suhonen: Beta-electron spectral shapes and the effective value of g_A

How do we extract information on the value of g_{A}?

These methods are now available:

For low momentum exchanges (g_{A}):

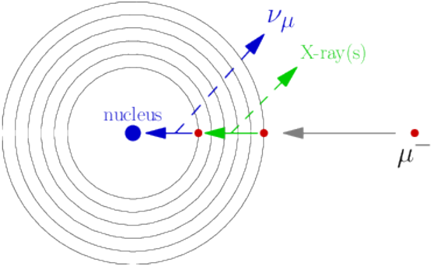
- study half-lives of β decays (1^+ and 2^- states)
- study half-lives of $2\nu\beta\beta$ decays (1^+ states)
- Study electron spectral shapes of β decays (J^π states)

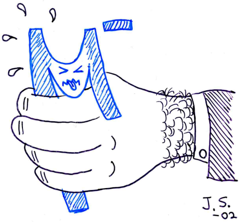
For high momentum exchanges like $0\nu\beta\beta$ decay ($g_{\mathrm{A},0\nu}$):

- Study nuclear muon capture (J^π states)

Jouni Suhonen: Beta-electron spectral shapes and the effective value of g_A

Ordinary Muon Capture (OMC)





Nuclear muon capture:

OMC: ${}^{A}_{Z}\mathrm{X} + \mu^- \rightarrow {}_{Z-1}^{\;\;\;A}\mathrm{Y} + \nu_\mu$

Also:

Muon decay: $\mu^- \rightarrow e^- + \bar{\nu}_e + \nu_\mu$ ($\tau = 2.2\mu$s)

OMC probability $\sim Z^4$
(in Fe 91% are captured,
breakeven at $Z \sim 11$)
